Journal Pre-proof

1 **OBJECTIVE:** A secondary analysis of the trial of randomized umbilical and fetal flow
2 in Europe suggested that the umbilicocerebral ratio (UCR) provides better
3 differentiation of neurodevelopmental outcome in the abnormal range compared to
4 cerebroplacental ratio (CPR).¹ However, the reported superiority of UCR is
5 controversial.² We aimed to compare the CPR and UCR for predicting operative
6 delivery for presumed fetal compromise and prolonged neonatal unit (NNU)
7 admission in term fetuses suspected to be small for gestational age (SGA).

8 **METHODS:** This was a retrospective analysis of singleton pregnancies with
9 estimated fetal weight less than the 10th centile (SGA) at 36 weeks' gestation or
10 beyond at St. George's Hospital in London between 1999 and 2015. CPR was
11 calculated as the ratio of middle cerebral artery and umbilical artery pulsatility index,
12 while UCR was calculated as the inverse of CPR. The outcomes were operative
13 delivery for presumed fetal compromise and prolonged NNU admission (admission to
14 the neonatal unit for longer than 48 hours).³ Multiples of medians (MoMs) were
15 calculated using the reference ranges reported by Acharya et al.⁴ The predictive
16 accuracy was assessed using receiver operating characteristics curves.

17 **RESULTS:** The analysis included 958 pregnancies. The incidence of operative
18 delivery and prolonged NNU admission were 17.6% (169/958) and 4.7% (45/958),
19 respectively. The CPR (median: 1.63 vs 1.51) and UCR (median: 0.61 vs 0.66)
20 values were significantly different in fetuses who underwent operative delivery for
21 presumed fetal compromise compared to those who did not ($P=0.015$ for both).
22 There were no statistically significant differences in either UCR or CPR between
23 those with and without prolonged NNU admission ($P=0.230$ for both). The number of
24 outlier values without MoM correction was significantly more with UCR compared to
25 CPR in those who did not have operative delivery for presumed fetal compromise
26 (5.6%, 44/789 vs. 1.6%, 13/789 $P<0.001$) or prolonged NNU admission (5.0%, 46/913
27 vs 1.5%, 14/913 $P<0.001$).

28 The area under the curve (AUC) values of UCR and CPR for predicting operative
29 delivery for presumed fetal compromise (AUC: 0.56, 95% CI: 0.51-0.61) or prolonged
30 NNU admission were the same (AUC: 0.55, 95% CI: 0.46-0.64) (Figure 1).

31 There was a significant decrease in the AUC values for predicting operative delivery
32 for presumed fetal compromise with UCR MoM (0.56 vs 0.53, $P<0.001$) or CPR MoM

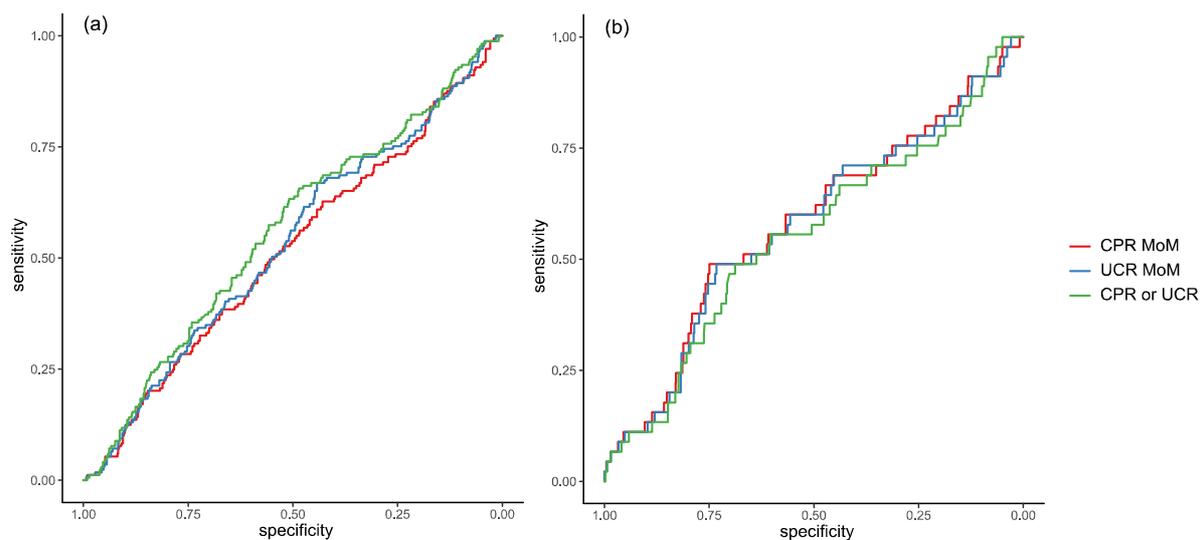

1 (0.56 vs 0.52, $P<0.001$) compared to raw values, while there was a significant
2 increase in AUC values for predicting prolonged NNU admission with UCR MoM
3 (0.57 vs 0.55, $P=0.036$) and CPR MoM (0.58 vs 0.55, $P=0.048$) compared to raw
4 values. There were no significant differences between UCR and CPR MoMs (P
5 $=0.176$).

6 **CONCLUSION:** The AUC values of CPR and UCR for predicting operative delivery
7 for presumed fetal compromise or prolonged NNU admission were essentially the
8 same. MoM standardization for gestational age changed the predictive accuracy for
9 prolonged NNU admission and operative delivery for presumed fetal compromise.
10 However, gestational age adjustment with MoM values may not be appropriate for
11 UCR and CPR when gestational age is an intermediate factor between exposures
12 and outcomes.⁵ The changes in the predictive accuracy are likely to be caused by
13 collider bias and may lead to erroneous conclusions.

2 **Figure 1.** The receiver operating characteristics (ROC) curves for operative delivery
3 for presumed fetal compromise (a) and prolonged neonatal unit admission (>48h) (b).
4 The cerebroplacental ratio (CPR) and umbilicocerebral ratio (UCR) had overlapping
5 ROC curves for operative delivery for presumed fetal compromise or prolonged
6 neonatal unit admission. The MoM standardization decreased the area under the
7 curve (AUC) values for operative delivery for presumed fetal compromise ($P<0.001$
8 for CPR and UCR), while they improved the AUC values for prolonged neonatal unit
9 admission ($P<0.05$ for CPR and UCR).
