<b>Abstract:</b>	<p>Kv7.4 channels are key determinants of arterial contractility and cochlear mechanosensation that, like all Kv7 channels, have an obligatory requirement for phosphatidylinositol 4, 5-bisphosphate (PIP<sub>2</sub>). βγ G proteins (Gβγ) have been identified as novel positive regulators of Kv7.4. The present study ascertained whether Gβγ increased Kv7.4 open probability through an increased sensitivity to PIP<sub>2</sub>. In HEK cells stably expressing Kv7.4 PIP<sub>2</sub> or Gβγ increased open probability in a concentration dependent manner. Depleting PIP<sub>2</sub> prevented any Gβγ-mediated stimulation whilst an array of Gβγ inhibitors prohibited any PIP<sub>2</sub>-induced current enhancement. A combination of PIP<sub>2</sub> and Gβγ at sub-efficacious concentration increased channel open probability considerably. The stimulatory effects of three Kv7.2-7.5 channel activators was also lost by PIP<sub>2</sub> depletion or Gβγ inhibitors. This study alters substantially our understanding of the fundamental processes that dictate Kv7.4 activity, revealing a more complex and subtle paradigm where the reliance on local phosphoinositide is dictated by interaction with Gβγ.</p>	
<b>Response to Reviewers:</b>	<p>The reviewers have been extremely diligent and this has improved our paper considerably. Thank you.</p> <p>We have amended all figures as suggested by the Reviewer. The numbers on the expanded inside out traces were actually to denote closed state and multiple open states. This has been added to each legend for clarification.</p> <p>All other points have been addressed or corrected.</p>

1       **Abstract:**  
2

3       Kv7.4 channels are key determinants of arterial contractility and cochlear  
4       mechanosensation that, like all Kv7 channels, have an obligatory requirement for  
5       phosphatidylinositol 4, 5-bisphosphate (PIP<sub>2</sub>). βγ G proteins (Gβγ) have been identified  
6       as novel positive regulators of Kv7.4. The present study ascertained whether Gβγ  
7       increased Kv7.4 open probability through an increased sensitivity to PIP<sub>2</sub>. In HEK cells  
8       stably expressing Kv7.4 PIP<sub>2</sub> or Gβγ increased open probability in a concentration  
9       dependent manner. Depleting PIP<sub>2</sub> prevented any Gβγ-mediated stimulation whilst an  
10       array of Gβγ inhibitors prohibited any PIP<sub>2</sub>-induced current enhancement. A combination  
11       of PIP<sub>2</sub> and Gβγ at sub-efficacious concentration increased channel open probability  
12       considerably. The stimulatory effects of three Kv7.2-7.5 channel activators was also lost  
13       by PIP<sub>2</sub> depletion or Gβγ inhibitors. This study alters substantially our understanding of  
14       the fundamental processes that dictate Kv7.4 activity, revealing a more complex and  
15       subtle paradigm where the reliance on local phosphoinositide is dictated by interaction  
16       with Gβγ.

44       **Introduction:**  
45

46       The Kv7 family of potassium channels (Kv7.1-Kv7.5) are crucial determinants of cardiac,  
47       neuronal, cochlear and vascular function [25, 26]. As such, defining the mechanisms that  
48       control how Kv7 channel activity is regulated is crucial. It is acknowledged that Kv7  
49       channels have an obligatory requirement for phosphatidylinositol 4, 5-bisphosphate  
50       (PIP<sub>2</sub>) [4, 12, 18] but we recently described how the Kv7.4 channel, important for normal  
51       vascular function [6, 7, 15], requires G-protein βγ subunits (Gβγ) for its voltage dependent

1 activity [27]. Few ion channels are directly regulated by  $G\beta\gamma$  with the best studied being  
2  
3 the G protein coupled inwardly rectifying potassium (GIRK) channel that controls  
4  
5 electrical excitability in neurons and cardiac cells [9-11, 19]. This channel is comprised  
6  
7 of Kir3.1 - 3.4 subunits and  $G\beta\gamma$  enhance open probability by stabilizing the interaction  
8  
9 of  $PIP_2$  [9, 13, 20]. We speculated whether the stimulatory effects of  $G\beta\gamma$  on Kv7.4 was  
10  
11 due to an interaction with  $PIP_2$  analogous to GIRK channels. As such,  $G\beta\gamma$  would be  
12  
13 ineffective under conditions where  $PIP_2$  levels were reduced. However, the study revealed  
14  
15 a level of regulation far more complex and provides the first account of a synergistic  
16  
17 regulation of Kv7.4 channels by  $G\beta\gamma$  and  $PIP_2$ .

## 26 **Methods:**

27  
28 *Cell culture.* Human embryonic kidney cells (HEK293) stably transfected with Kv7.4  
29  
30 were maintained in modified Eagles' medium containing 10% Foetal calf serum, 1%  
31  
32 penicillin/streptomycin, 1% non-essential amino acids, 1% L-glutamine and 1% sodium  
33  
34 pyruvate. For experiments, cells were detached by brief trypsin treatment. HEK Kv7.4  
35  
36 cells were plated on 13mm coverslips in an external physiological salt solution (PSS)  
37  
38 containing (mM): KCl 6, NaCl 120,  $MgCl_2$  1.2,  $CaCl_2$  2.5, D-glucose 12 and HEPES 10,  
39  
40 pH was adjusted to 7.35 with NaOH. Cells were left on cover slips for 30mins at room  
41  
42 temperature and stored at 4°C for up to 8 hours.  
43  
44  
45  
46  
47  
48  
49  
50

51 *Whole-cell Electrophysiology.* Macroscopic transmembrane ionic currents of HEK293  
52  
53 Kv7.4 cells were recorded using standard amphotericin B (300  $\mu$ g/ml) perforated-patch  
54  
55 techniques in voltage-clamp mode. In some experiments the ruptured whole-cell patch-  
56  
57 clamp technique was used for intracellular perfusion of active  $G\beta\gamma$  subunits. Patch  
58  
59  
60  
61

1 pipettes were fire-polished and had a resistance of 4-8 M $\Omega$  when filled with the pipette  
2  
3 solution of the following composition (mM): KCl 126, MgCl<sub>2</sub> 1.2, HEPES 10, EGTA 0.5,  
4  
5 pH was adjusted to 7.2 with KOH. 1 mM of Na<sub>2</sub>ATP was added to the pipette solution  
6  
7 for the ruptured whole-cell experiments. Cells were held at -60 mV and current amplitude  
8  
9 was monitored by application of test pulse to +20 mV. To generate current-voltage  
10  
11 relationships a voltage step protocol was used from a holding potential of -60 mV testing  
12  
13 a range of voltages from -90 to +40 mV in 10mv increments at 15s intervals. Drugs were  
14  
15 applied in the external solution using a bath perfusion system, except for G $\beta$  $\gamma$  subunits  
16  
17 which were included in the pipette solution.  
18

20  
21  
22  
23  
24

25 *Single channel electrophysiology.* Single channel activity of Kv7.4 currents expressed in  
26  
27 HEK293 cells was recorded in voltage-clamp mode using inside-out patch configuration  
28  
29 in an external solution of the following composition (mM): KCl 165, HEPES 5, EGTA  
30  
31 10, pH was adjusted to 7.2 with NaOH. Patch pipettes were fire-polished and had a  
32  
33 resistance of around 20 M $\Omega$  when filled with PSS as a pipette solution. Cells were voltage  
34  
35 clamped at 0mV. Cell-attached patch configuration was used in some experiments. In this  
36  
37 case PSS was used for both, pipette and bath solutions and the cells were recorded at -  
38  
39 50mV, so the expected membrane potential under the patch is around -6mV (assuming  
40  
41 resting membrane potential of -56mV [21]). All single-channel current records were  
42  
43 filtered at 0.1 kHz using a Frequency Devices 9002 digital filter with 8-pole lowpass  
44  
45 Bessel filter and acquired at 1 kHz (Axopatch 200B 4-pole lowpass Bessel filter). Current  
46  
47 amplitudes were calculated from idealized traces of  $\geq$  180s in duration using 50%  
48  
49 threshold method using pClamp 9.0 software. Events lasting less than 6.664 ms ( $2 \times$  rise  
50  
51 time for a 100 Hz, -3 db, low pass filter, [8]) were excluded from the analysis to maximize  
52  
53  
54  
55  
56  
57  
58  
59  
60  
61  
62

1 the number of channel openings reaching their full current amplitude. Channel activity  
2  
3 was expressed as NPo, which was calculated automatically and reported by the pClamp  
4  
5 9.0 software under “event statistics” after completion of the single-channel search  
6  
7 procedure applied to the idealized traces  $\geq 180$ s in duration at each condition. All whole-  
8  
9 cell and single channel current recordings were made using AXOpamp 200B amplifier  
10  
11 (Axon Instruments) at room temperature. Electrical signals were generated and digitized  
12  
13 using a Digidata 1322A hosted by a PC running pClamp 9.0 software (Molecular  
14  
15 Devices). Drugs were applied in the external solution using a push-pull system. All  
16  
17 electrophysiological data were analysed and plotted using pClamp 9.0, MicroCal Origin  
18  
19 6.0 (MicroCal Software, Northampton, MA, USA) and GraphPad Prism (GraphPad  
20  
21 Software, Inc., La Jolla, CA, USA). PIP<sub>2</sub> and  $\beta\gamma$  G proteins were applied at a range of  
22  
23 concentrations to inside-out excised patches to determine the sensitivity of the Kv7.4  
24  
25 channel to these modulators. However, it was not usually possible to hold the patch long  
26  
27 enough to do a full concentration-response and saturating responses were not achieved.  
28  
29 Data are therefore accumulated from a number of patches and plotted by a sigmoidal  
30  
31 curve to give an approximate estimate of sensitivity. Values for half maximal stimulation  
32  
33 taken from these fits are quoted in the text with the caveat that saturation of channel  
34  
35 enhancement was not seen with either molecule.

45  
46

47 *In-cell Western blot.* In-cell Western blot experiments were performed as described  
48  
49 elsewhere [5]. HEK293 cells stably expressing Kv7.4 were grown in 96-well plates for  
50  
51 24h and incubated with different drugs as indicated. After treatment, cells were fixed with  
52  
53 3% ice-cold paraformaldehyde for 10 min at room temperature (RT, 22-24°C), washed  
54  
55 with PBS and blocked/permeabilised with PBS containing 5% bovine serum albumin  
56  
57  
58  
59  
60  
61

1 (BSA) and 0.2% Triton X-100 for 1h at RT. Cells were subsequently incubated for 14-  
2  
3 16h at 4°C with the following primary antibodies: mouse anti PIP<sub>2</sub> (2C11, dil 1:200, Santa  
4  
5 Cruz, Dallas, USA) and rabbit anti cytochrome c oxidase subunit IV (COX-IV, dil 1:1000,  
6  
7 Abcam, Cambridge, UK). After 3 washes with PBS (10min each), cells were incubated  
8  
9 with anti-mouse and anti-rabbit IgG conjugated to IRDye® 680RD and IRDye® 800CW,  
10  
11 respectively (dil 1:1000, Li-Cor, Cambridge, UK), for 1h at RT. All antibodies were  
12  
13 diluted in PBS containing 1% BSA and 0.04% Triton X-100. Cells were then washed 3  
14  
15 times with PBS and imaged on the Odyssey Infrared Imaging System (Li-Cor,  
16  
17 Cambridge, UK) and analysed with supplier's software (Version 3.1).  
18  
19  
20  
21  
22  
23  
24

25 *Statistical analysis.* All data are mean ± s.e.m. of n cells. One-way ANOVA test followed  
26  
27 by a Dunnett's or Tukey's multiple comparisons test or Student's t-test were used to  
28  
29 determine statistical significance between groups, where \* =  $P < 0.05$ , \*\* =  $P < 0.01$ , \*\*\*  
30  
31 =  $P < 0.001$  and \*\*\*\* =  $P < 0.0001$ .  
32  
33  
34  
35  
36

37 **Reagents.** Many different pharmacological tools were used to either alter PIP<sub>2</sub> levels or  
38  
39 impair βγ G protein interactions. These are listed below with the supplier and  
40  
41 mechanism of action.  
42  
43  
44

45 *PIP<sub>2</sub> depletion.* Wortmannin (Sigma Aldrich, Poole, UK), at 20 μM is an inhibitor of  
46  
47 myosin light chain kinase, phosphatidylinositol 3-kinase and phosphatidylinositol 4-  
48  
49 kinase. It depletes PIP<sub>2</sub> levels by inhibiting synthesis from phosphatidyl inositol via the  
50  
51 phosphatidylinositol 4-kinase [1, 21, 28]. PIP<sub>2</sub> depletion was augmented by brief  
52  
53 application of 100 μM trypsin that activates protease activated receptors endogenous to  
54  
55 the HEK cell [30]. In addition, the phospholipid acceptor α-Cyclodextrin, and LY-  
56  
57  
58  
59  
60  
61  
62  
63  
64  
65

1 294,002 hydrochloride, another inhibitor of phosphatidylinositol kinase (both from  
2  
3 Sigma) were used for in-cell western blot studies.  
4  
5

6  
7 *Prevention of  $\beta\gamma$  G protein interaction.* We used a range of structurally different  
8  
9 compounds that prevent  $\beta\gamma$  G proteins interacting with effector proteins through  
10  
11 different mechanisms.  $G\beta\gamma$ -target recognition is defined by a single “hotspot”, which  
12  
13 has distinct sub-surfaces for individual G protein subunit interactions [3]. Gallein  
14  
15 (Tocris, Avonmouth, UK), M201 and M119K (provided by National Cancer Institute  
16  
17 Drug Development Programme, 3) all bind to the hot spot at concentrations less than 1  
18  
19  $\mu$ M but differentially modulate  $G\beta\gamma$  interactions with effectors [3]. Grk2i (Tocris,  
20  
21 Avonmouth, UK, 10  $\mu$ M) is a peptide analogue of the G-protein receptor kinase c-  
22  
23 terminus [16] which competes with effector proteins for  $\beta\gamma$  G protein binding. All  
24  
25 reagents were applied to the bathing solution at concentrations derived from previous  
26  
27 publications.  
28  
29  
30  
31  
32

33  
34  
35 *Additional Materials.* G-protein  $\beta\gamma$  subunits from bovine brain was purchased from  
36  
37 Merck.  $PIP_2$  (D-*myo*-Phosphatidylinositol 4,5-bisphosphate) was purchased from  
38  
39 Echelon. HEK293 cells stably expressing Kv7.4 were a gift from the University of  
40  
41 Copenhagen [2, 24]. Retigabine, S-1 and NS15370 were synthesised by NeuroSearch  
42  
43 A/S, (Ballerup, Denmark). The pan-Kv7 blocker linopirdine was purchased from Tocris  
44  
45 (Avonmouth, UK).  
46  
47  
48

## 49 **Results:**

50  
51  
52  *$PIP_2$  depletion abolishes Kv7.4 currents and prevents their activation by  $G\beta\gamma$ .*

53  
54  
55  
56 In HEK cells stably expressing Kv7.4, depolarisation evoked characteristic time-  
57  
58 dependent currents (Fig 1) that were abolished by treatment with the Kv7 blocker  
59  
60

1 linopirdine (10  $\mu$ M) and were not apparent in untransfected HEK cells [27]. Application  
2  
3 of 20  $\mu$ M wortmannin, to reduce PIP<sub>2</sub> levels gradually decreased Kv7.4 currents recorded  
4  
5 in perforated-patch whole cell configuration (Fig. 1A) Further inhibition of currents to a  
6  
7 level identical to that recorded after application of the Kv7 channel blocker linopirdine  
8  
9 (10  $\mu$ M) was achieved by brief ( $\leq$  30 s) application of 1  $\mu$ M trypsin to stimulate  
10  
11 endogenous G-protein-coupled proteinase-activated receptors (Fig 1B). Wortmannin also  
12  
13 reduced Kv7.4 channel activity in cell-attached experiments (Fig 1C). In-cell Western  
14  
15 analysis showed that wortmannin alone and in the combination with trypsin application  
16  
17 significantly decreased levels of PIP<sub>2</sub> in Kv7.4 transfected HEK cells (Fig 1D). We then  
18  
19 investigated whether PIP<sub>2</sub> depletion modified the stimulatory response to enrichment of  
20  
21 internal solutions with G $\beta\gamma$ . Like our previous study [27] intracellular perfusion of active  
22  
23 G $\beta\gamma$  (250 ng/ml) increased current amplitude by ~70 % within 5 mins of rupture in control  
24  
25 cells (Fig 2Aa, B) but had considerably less effect (~38 % increase) in cells incubated  
26  
27 with 20  $\mu$ M wortmannin (Fig 2Ab, B). We then undertook inside-out excised patch  
28  
29 recording to investigate this effect further. In HEK cells stably expressing Kv7.4 but not  
30  
31 untransfected cells robust K<sup>+</sup> channel activity was recorded immediately upon patch  
32  
33 excision that usually decayed within 1-2 minutes to a steady, lower level of activity. This  
34  
35 is considered to be due to the wash out of key intracellular mediators from the membrane  
36  
37 patch [4, 12, 18]. Bath application of G $\beta\gamma$  (0.4-50 ng/ml) increased channel activity in a  
38  
39 concentration-dependent manner similar to previous work [27] with an estimated value  
40  
41 for half maximal stimulation of 8.1 ng/ml (n=4-7, Fig. 3A, B). However, bath application  
42  
43 of G $\beta\gamma$  had no effect ( $2.51 \pm 0.05\%$  increase only, n=4) on the negligible channel activity  
44  
45 recorded in the continued presence of wortmannin (Fig 3C) whereas application of  
46  
47 exogenous PIP<sub>2</sub> in the continued presence of wortmannin re-established channel activity  
48  
49  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60  
61  
62  
63  
64  
65

1 (Fig. 3D, n=5). These data show that inhibition of PIP<sub>2</sub> re-synthesis by wortmannin  
2  
3 decreased PIP<sub>2</sub>, reduced channel activity and prevented Gβγ –mediated channel  
4  
5 stimulation suggesting that Gβγ may act upstream of PIP<sub>2</sub>.  
6  
7

8  
9 *Gβγ inhibition abolishes Kv7.4 currents and prevents their activation by PIP<sub>2</sub>.*

10  
11 Having established that PIP<sub>2</sub> depletion impaired Gβγ-mediated enhancement of Kv7.4  
12  
13 currents we addressed whether reduction of Gβγ activity limited the well-established  
14  
15 PIP<sub>2</sub>-enhancement of channels. Initially we used the in-cell Western blot technique to  
16  
17 ascertain whether Gβγ inhibitors altered PIP<sub>2</sub> levels. Figure 4A shows that neither Grk2i,  
18  
19 M201 nor M199K altered PIP<sub>2</sub> levels whilst the well-used small molecule Gβγ inhibitor  
20  
21 gallein reduced PIP<sub>2</sub> to some extent. In a previous study, we showed that gallein, Grk2i  
22  
23 and an antibody raised against Gβ inhibited whole cell Kv7.4 currents markedly [27].  
24  
25 Application of two novel and potent Gβγ inhibitors M201 and M119K [3] also inhibited  
26  
27 whole cell Kv7.4 currents significantly (Fig. 4B, C). Figure 4C shows the accumulated  
28  
29 data for all Gβγ inhibitors on whole cell Kv7.4 currents highlighting the suppressive effect  
30  
31 irrespective of mechanistic action. Having established the effect of Gβγ inhibitors on  
32  
33 whole cell currents we then performed inside-out recordings to determine how single  
34  
35 channel activity was affected. Figure 4 D and E shows that M201 and Grk2i reduced the  
36  
37 open probability of Kv7.4 channels in excised patches to negligible levels similarly to the  
38  
39 action of gallein [27] (Fig. 4F).  
40  
41  
42  
43  
44  
45  
46  
47  
48

49 Having confirmed that inhibition of Gβγ inhibited Kv7.4 currents recorded at the  
50  
51 whole cell and single channel level we used inside-out excised patches to ascertain if  
52  
53 structurally different Gβγ inhibitors altered PIP<sub>2</sub>-induced enhancement of Kv7.4 activity.  
54  
55 Under control conditions application of PIP<sub>2</sub> increased the apparent channel open  
56  
57 probability (NPo) of the Kv7.4 channel activity in a concentration-dependent manner (Fig  
58  
59  
60  
61

1 5A, B). This resulted in an estimated value for half-maximal stimulation of 117  $\mu\text{M}$  (n=4-  
2  
3 11) similar to previous papers [4, 12, 18]. By comparison, no significant increase in Kv7.4  
4  
5 channel activity was observed upon application of PIP<sub>2</sub> (10-100  $\mu\text{M}$ ) in patches incubated  
6  
7 in M201, gallein or Grk2i (Fig 5C-F). These data reveal that inhibition of G $\beta\gamma$  interaction  
8  
9 by structurally and mechanistically different agents not only inhibits Kv-7.4 basal activity,  
10  
11 but also prevented PIP<sub>2</sub> stimulation of Kv7.4 (Fig 5F).  
12  
13

14  
15  
16 *PIP<sub>2</sub> and G $\beta\gamma$  are synergistic regulators of Kv7.4 channels.*  
17

18  
19 Our data thus far suggest that rather than regulation of Kv7.4 by PIP<sub>2</sub> and G $\beta\gamma$  being a  
20  
21 linear relationship the signal molecules combine to dictate channel function. The next  
22  
23 series of inside-out experiments aimed to determine if a low sub-effective concentration  
24  
25 of G $\beta\gamma$  could enhance the sensitivity of the channel to exogenous PIP<sub>2</sub>. Application of  
26  
27 low concentrations of either G $\beta\gamma$  (1 ng/ml) or PIP<sub>2</sub> (1-3  $\mu\text{M}$ ) to inside-out patches had a  
28  
29 negligible effect on Kv7.4 channel activity (Fig 6). However, Figure 6 B-D shows that in  
30  
31 combination a marked increase in channel activity was observed and the presence of 1  
32  
33 ng/ml G $\beta\gamma$  increased the sensitivity of the channel to PIP<sub>2</sub>. For instance, NPo increased  
34  
35 to  $0.29 \pm 0.07$  (n=6) when 3  $\mu\text{M}$  PIP<sub>2</sub> was applied in the presence of 1 ng/ml G $\beta\gamma$ , which  
36  
37 was significantly greater than NPo when 3  $\mu\text{M}$  of PIP<sub>2</sub> alone was applied ( $0.077 \pm 0.02$ ,  
38  
39 n=8, Fig 6C). The stimulatory effect of G $\beta\gamma$  was not apparent when 100  $\mu\text{M}$  PIP<sub>2</sub> was  
40  
41 applied suggesting the combinational effect had a functional ceiling (Fig 6D).  
42  
43 Consequently, low concentrations of G $\beta\gamma$  produced a leftward shift in the sensitivity of  
44  
45 the Kv7.4 channel to PIP<sub>2</sub> suggesting the two molecules acted synergistically.  
46  
47  
48  
49  
50  
51

52  
53  
54 *PIP<sub>2</sub> depletion and reduced G $\beta\gamma$  activity affects pharmacological modulation of Kv7.4.*  
55  
56  
57  
58  
59  
60  
61

1 Application of three structurally different enhancers of Kv7.2-7.5, S-1, retigabine and  
2  
3 NS15370, produced a marked increase in whole cell currents in HEK cells stably  
4  
5 expressing Kv7.4 with currents at +20 mV increasing by approximately 40 % (Fig 7). In  
6  
7 cells treated with wortmannin alone some enhancement with each activator was observed.  
8  
9 However, in cells bathed in either wortmannin plus trypsin or gallein alone the  
10  
11 stimulatory effect of all three agents was abrogated. Consequently, the ability of  
12  
13 pharmacological agents to augment Kv7.4 was compromised by PIP<sub>2</sub> depletion or  
14  
15 reduced  $\beta\gamma$  subunit activity.  
16  
17  
18  
19  
20

## 21 **Discussion:**

22  
23 It is accepted dogma that Kv7 channels have an obligatory reliance on PIP<sub>2</sub> for effective  
24  
25 function. We now reveal that this positive regulation occurs synergistically with G $\beta\gamma$  and  
26  
27 there is an obligatory reliance on both mediators to be present for effective channel  
28  
29 function. These findings change radically our understanding on how Kv7.4 channels are  
30  
31 regulated. If other Kv7 channels are also affected by G $\beta\gamma$  in a similar manner the findings  
32  
33 of the present study will have wide ranging implications as Kv7 channels regulate cellular  
34  
35 physiology in many cell types. We show by in-cell Western blot that treatment with the  
36  
37 phosphatidylinositol-4-kinase inhibitor wortmannin and stimulation of G-protein coupled  
38  
39 receptors with trypsin reduced global PIP<sub>2</sub>, and reduced Kv7.4 currents to negligible  
40  
41 levels (Fig 1). More importantly this treatment abrogated the stimulatory effect of G $\beta\gamma$   
42  
43 on Kv7.4 channels but did not impair the ability of exogenous 100  $\mu$ M PIP<sub>2</sub> (Fig 3) to  
44  
45 enhance Kv7.4 channel activity in excised patches. This implied PIP<sub>2</sub> sensitization  
46  
47 underlies the positive effect of G $\beta\gamma$ . However, treatment with structurally and  
48  
49 mechanistically different inhibitors of G $\beta\gamma$  interactions (gallein, M201, M199K and  
50  
51 Grk2i) also decreased Kv7.4 channel activity (Figs 3 & 4) to the same levels as treatment  
52  
53

1 with wortmannin and trypsin, which mirrored the inhibition produced by the Kv7 channel  
2 blocker linopirdine. Moreover, all Gβγ inhibitors prevented any increase in channel  
3 activity by exogenous PIP<sub>2</sub> (100 μM) in excised patches (Fig 5). It is worth stressing that  
4 these inhibitors disable Gβγ interactions with target proteins through different binding  
5 domains and mechanisms [3] consistent with Gβγ having differential protein effector sites  
6 but all suppressed PIP<sub>2</sub>-induced enhancement of Kv7.4 open probability. These findings  
7 suggested that PIP<sub>2</sub> was not simply an upstream channel regulator. In fact, these findings  
8 reveal that inherent Kv7.4 channel activity is dictated by a coordinated interaction with  
9 PIP<sub>2</sub> and Gβγ. Removal of either regulatory arm leads to progressive run down of channel  
10 activity and refractoriness to stimulation by either molecule. The synergistic effect of PIP<sub>2</sub>  
11 and Gβγ was substantiated by the observation that a sub-eficacious dose of Gβγ (1 ng/ml)  
12 potentiated the response to a low concentration of PIP<sub>2</sub> (1-10 μM) but not a saturating  
13 dose of PIP<sub>2</sub> (100 μM) resulting in a pronounced leftward shift in the response to  
14 exogenous PIP<sub>2</sub> (Fig 6).

34  
35  
36 In addition to the control of Kv7.4 activity at rest we also show that compounds  
37 that activate Kv7.2-7.5 through a common molecular mechanism [14, 17, 22, 33] also  
38 required PIP<sub>2</sub> and Gβγ binding to be effective. These findings corroborate previous work  
39 that showed retigabine-induced stimulation of Kv7.2/ or 7.3, which comprise the neuronal  
40 M-channel, was negligible after PIP<sub>2</sub> depletion [35]. Interestingly the pharmacological  
41 dependence on PIP<sub>2</sub> was localized to an interaction site more proximal than the well-  
42 established C-terminus site necessary for channel activity [35]. It is possible that the  
43 synergistic effect of Gβγ is due to alterations of endogenous levels of PIP<sub>2</sub> and Gβγ do  
44 activate phospholipase Cβ and Phosphoinositide-3-kinase [23]. However, these enzymes  
45 would reduce rather than enhance PIP<sub>2</sub> levels. Moreover, the Gβγ inhibitors M201,

1 M199K and Grk2i had no discernible effect on PIP<sub>2</sub> levels whereas gallein decreased  
2  
3 global PIP<sub>2</sub>. This effect of gallein has not been reported previously and there is no reason  
4  
5 for the effect. The fact that other Gβγ inhibitors did not alter global PIP<sub>2</sub> levels suggests  
6  
7 it is a quirk of the molecule rather than of Gβγ inhibition.  
8  
9

10  
11 The dual regulation of Kv7.4 by PIP<sub>2</sub> and Gβγ identified in the present study bears  
12  
13 a considerable similarity to GIRK channels, which have a co-dependence on Gβγ and  
14  
15 PIP<sub>2</sub> [10, 20]. Early studies proposed that Gβγ stabilized the PIP<sub>2</sub> interaction with Kir3.1  
16  
17 / Kir3.4 [13, 29]. Crystallographic studies revealed that full GIRK activation was reliant  
18  
19 upon PIP<sub>2</sub> interacting with an internal gate independent of the G-gate where Gβγ bind and  
20  
21 no channel openings occurred if either gate was unoccupied [31, 32]. Currently the same  
22  
23 level of molecular insight does not exist for Kv7.4. PIP<sub>2</sub> binding domains have been  
24  
25 identified in other Kv7 family members but this information is lacking for Kv7.4. In  
26  
27 addition, there is no information on binding sites for Gβγ. In GIRK channels  
28  
29 approximately 12 sites across the protein have been identified as important for Gβγ  
30  
31 binding that combine to accommodate 4 Gβγ molecules in the functional tetramer [9, 34].  
32  
33 Moreover, distinct high- and low-affinity sites exist in GIRKs that determine basal  
34  
35 activation and receptor-mediated activation, respectively [11]. These aspects of molecular  
36  
37 recognition need to be determined for Kv7.4.  
38  
39  
40  
41  
42  
43  
44  
45

46 A criticism that could be levelled at this study is it relies solely on  
47  
48 pharmacological agents for the conclusion. However, we use blockers that are not only  
49  
50 structurally different but which work through varied mechanisms. As wortmannin and  
51  
52 various inhibitors of Gβγ reduced Kv7.4 channel activity to negligible levels there must  
53  
54 be sufficient PIP<sub>2</sub> and Gβγ in the channel locality to sustain channel activity under excised  
55  
56 patch conditions. It is generally assumed that PIP<sub>2</sub> levels remain consistent in a normal  
57  
58  
59  
60  
61

1 healthy cell and are replenished rapidly upon hydrolysis. Our data show that Kv7.4  
2  
3 activity is attenuated by Gβγ inhibitors implying that there is a persistent influence of Gβγ  
4  
5 maintaining channel activity. Again, there is a parallel with GIRK channels that have a  
6  
7 basal level of activity due to constitutive binding of Gβγ [11]. The free Gβγ maintaining  
8  
9 Kv7.4 activity may be the product of binding of Gα to the channel protein and the  
10  
11 associated tethering of Gβγ as shown for Kir3.1 [11], localised G-protein coupled receptor  
12  
13 activity or a labile free pool of Gβγ. Irrespective of these unknowns we have identified  
14  
15 that Kv7.4 activity is crucially dependent on a synergistic interplay between PIP<sub>2</sub> and  
16  
17 Gβγ. Kv7 channels are well known to have an obligatory requirement for PIP<sub>2</sub> but this  
18  
19 study reveals a more complex and subtle paradigm where the reliance on local  
20  
21 phosphoinositide is dictated by an involvement of Gβγ. Whilst the present study focuses  
22  
23 on heterologous expression the findings have physiological implications because Kv7  
24  
25 channel isoforms have a key role in many cell types. Kv7.1 comprises the late repolarising  
26  
27 component of the cardiac action potential, Kv7.2/7.3 and Kv7.5/7.3 heteromers constitute  
28  
29 the M-channel in neurones and Kv7.4 has a role in cochlear as well as arterial reactivity.  
30  
31 Dysregulation of these channels impacts considerably on cellular activity in each cell type  
32  
33 under consideration. Defining the mechanisms that regulate Kv7 channels is therefore  
34  
35 paramount for understanding physiological and pathophysiological processes. We have  
36  
37 already established that βγ G proteins modulate endogenous Kv7 channels in arterial  
38  
39 smooth muscle cells consistent with their effects on heterologously expressed Kv7.4 [24]  
40  
41 and it is likely that similar effects occur on native Kv7 channels in other systems. If this  
42  
43 is the case, then revelation of the present study will have profound resonance for cellular  
44  
45 regulation.

4 **Figure 1. PIP<sub>2</sub> depletion reduces Kv7.4 currents.**

5  
6 A, Examples of whole cell K<sup>+</sup> currents from HEK293 Kv7.4 cells evoked by step  
7 depolarisation from -60 mV to +20 mV in the absence (a) and presence of 20 μM  
8 wortmannin (b). Currents were recorded every 15 s and wortmannin applied after 60 s.  
9  
10 Initial current trace shown in black in both panels. Subsequent traces after 5, 10 and 20  
11 min intervals are shown in blue, green and red, correspondingly. Panel (c) shows the mean  
12 amplitude of K<sup>+</sup> current at +20 mV in the absence (black) and presence of wortmannin  
13 (red). Each point is the mean ± s.e.m. of 4 cells. B, Representative traces of Kv7.4 currents  
14 evoked by steps from -60 mV to a range of potential (-90 to +40 mV) in control (a) and  
15 after depletion of PIP<sub>2</sub> by the cells pre-incubation with wortmannin + short (≤ 30 s)  
16 application of trypsin (b). The mean data are shown in panel (c) with control (black,  
17 n=22), wortmannin alone (green, n=34), wortmannin plus trypsin (red, n=36) and  
18 linopirdine (purple, n= 14). C, Example of cell-attached patch recording from HEK293  
19 Kv7.4 cell showing effect of 20 μM wortmannin. Long term trace is shown in panel (a).  
20 Representative expanded 1.75 s segments of channel openings taken from panel (a)  
21 highlighting channel activity in the absence and presence of wortmannin are shown in  
22 panels (b) and (c). Closed state and multiple open states are denoted by C and O1-O6. D,  
23 In-cell Western analysis showing that wortmannin, and other known PIP<sub>2</sub> inhibitors,  
24 decrease global PIP<sub>2</sub> level in HEK293 Kv7.4 cells (n=12-23).
