Running Title:

Progression of Doppler in early-onset fetal smallness.

Word count: Word count: 3052, Table count: 3, Figure count: 5.

For Peer Review Only

ABSTRACT

Objective: To evaluate the progression of Doppler abnormalities in early-onset fetal smallness (SGA).

Methods: 948 Doppler examinations of the umbilical artery (UA), middle cerebral artery (MCA) and ductus venosus (DV), belonging to 405 early-onset SGA fetuses, were studied, evaluating the sequences of Doppler progression, the interval examination-labor at which Doppler became abnormal and the cumulative sum of Doppler anomalies in relation with labor proximity.

Results: The most frequent sequences were that in which only the UA pulsatility index (PI) became abnormal (42.1%) and that in which an abnormal UA PI appeared first, followed by an abnormal MCA PI (24.2%). In general, 71.3% of the fetuses followed the classical progression sequence UA→MCA→DV, mostly in the early stages of growth restriction (84.1%). In addition, the UA PI was the first parameter to be affected (9 weeks before delivery), followed by the MCA PI and the DV PIV (1 and 0 weeks). Finally, the UA PI began to sum anomalies 5 weeks before delivery, while the MCA and DV did it at 3 and 1 weeks before the pregnancy ended.

Conclusion: In early-onset SGA fetuses, Doppler progression tends to follow a predictable order, with sequential changes in the umbilical, cerebral and ductus venosus impedances.

INTRODUCTION

Growth restriction imposes an adaptive burden on fetal hemodynamics, which aims to improve intrauterine survival¹. This strain has been recently characterized and divided from a physiopathological point of view in two different conditions². Late-onset fetal growth restriction (FGR) occurs more frequently, and is characterized by a state of nutritional imbalance with a preserved or mildly impaired placental function. The middle cerebral artery (MCA) Doppler and the cerebroplacental ratio (CPR) are usually the first to be affected in these pregnancies, while the umbilical artery (UA) Doppler pulsatility index (PI) remains normal or mildly increased³. On the other extreme, early-onset FGR is initiated by placental dysfunction, resulting in anomalies of the UA blood flow, followed by changes in the MCA PI and the CPR in the so-called “brain-sparing phenomenon”. If restriction progresses, the left ventricle becomes dominant, and the flow in the aortic isthmus becomes reverted. Finally, late adaptive changes include an increase in the ductus venosus pulsatility index of the vein (DV PIV), reflecting different degrees of cardiac failure, which in severe cases anticipate fetal death⁴⁻¹⁰.

This scenario of hemodynamic changes in early-onset fetal growth restriction was generally accepted for long as the most frequent. However it has been recently challenged¹¹, suggesting that no specific sequence of Doppler progression among the participant vessels was more frequent than the other. The purpose of the study was to evaluate the progression of hemodynamic changes in small for gestational age (SGA) fetuses.

MATERIAL AND METHODS

In a retrospective study, 948 Doppler examinations of the UA PI, MCA PI and DV PIV were performed between 24 and 33 weeks (24⁺⁰-33⁺⁶ days) in 405 early-onset SGA fetuses attending the ultrasound and prenatal diagnosis units of two tertiary centers in the UK (London) and Spain (Valencia). All fetuses had an estimated fetal weight (EFW) at examination below the 10th centile according to Hadlock 4 formula¹² and were delivered prior to 37 weeks' gestation (36⁺⁶ days). The birth weight of all these fetuses was confirmed to be below the 10th centile at delivery. Fetuses affected with aneuploidy or major structural abnormalities were not included. As the object of the study was the evaluation of Doppler progression towards abnormal values, for every fetus and regardless of the number of examinations, we took into account only the first time the UA PI, MCA PI and DV PI crossed their abnormal percentiles (>95th centile for the UA PI, >95th centile for the DV PIV and <5th centile for the MCA PI). We acknowledge this was not the only way to analyze data, however we considered this methodology depicted better the order of Doppler progression.

The limit percentile values were calculated for each week of gestational age (GA) according to the following formulas¹⁴⁻¹⁶:

$$\text{UA PI P95} = 2.6075 - 0.061129 * \text{GA} + 0.00057877 * \text{GA}^2$$

$$\text{MCA PI P5} = -1.404152194 + 0.209338699 * \text{GA} - 0.003768618 * \text{GA}^2$$

$$\text{DV PIV P95} = 0.69054 + 0.01431 * \text{GA} - 0.00035751 * \text{GA}^2$$

Where GA indicated the gestational age at examination expressed in weeks

For every fetus, we studied the order in which the three Doppler parameters became abnormal and calculated for all fetuses the frequency of all possible

1
2
3 combinations of Doppler progressions. In other words, the number of times a
4 specific sequence of Doppler anomalies followed a specific order, including
5 those in which only one, two or the three vessels were abnormal. Importantly,
6 we considered the existence of an abnormal Doppler value when it was found
7 abnormal for the first time, even though this parameter became normal in any
8 of the following examinations, e.g. following the administration of steroids.
9
10
11
12
13
14

15
16 Management of cases with two or more abnormal Doppler parameters in the
17 same examination.
18
19

20
21 In case that two or three Doppler parameters were abnormal at the same time
22 the parameter that showed a higher statistical difference with its limit
23 percentile was considered first in the sequence to become abnormal. This
24 was also the methodology followed in fetuses with only one or with few
25 examinations.
26
27
28
29
30

31
32 Management of fetuses with only one examination
33

34 Although we initially thought that only fetuses with multiple examinations could
35 inform about Doppler progression (like small sequences of Doppler changes
36 that could be collected and studied) in fact fetuses with only one examination
37 were also interesting. The methodology applied to obtain information of
38 progression in these cases used again the statistical differences with the
39 respective abnormal percentiles to evaluate which Doppler parameter had
40 earlier become abnormal.
41
42
43
44
45
46
47
48

49 For example: let us consider that in a fetus with only one examination at week
50 32 the DV Doppler was normal ($<p_{95}$) and the UA and MCA Doppler were
51 both abnormal (respectively $>p_{95}$ and $<p_5$). So the progression order could
52 be either UA→MCA or MCA→UA. In order to know which parameter had
53
54
55
56
57
58
59
60

1
2
3 been the first to become abnormal we calculated the statistical difference with
4 the respective limit percentile (the 5th percentile for the MCA, and the 95th
5 percentile for the UA Doppler). If the difference with this limit percentile was
6
7 for example minimal in the UA Doppler, and more important in the MCA
8 Doppler, this meant that the MCA had probably become abnormal earlier.
9
10 Therefore, the sequence of activation in this fetus might be expressed as
11
12 MCA→UA.
13
14
15
16
17

18 This was done in all fetuses with a single examination, being these sequences
19 incorporated to the general sum of sequences in order to evaluate the general
20 order of Doppler progression. In fetuses with two or more examinations the
21 same procedure was applied. However, in these cases only the first abnormal
22 examination (the first time the Doppler value became abnormal) was taken
23 into account.
24
25
26
27
28
29
30

31 We were aware that these calculations were based on statistical assumptions
32 however as the errors were applicable to the three Doppler parameters, we
33 considered that the final bias introduced in the total sum of Doppler
34 progression represented just a small deviation from real order in fetuses with
35 multiple examinations.
36
37
38
39
40
41
42

43 Apart from this general order, we also evaluated the frequency of fetuses with
44 any abnormal Doppler, the frequency of fetuses following the classical
45 sequence (UA→MCA→DV) among those with any abnormal Doppler, the
46 frequency of fetuses following the classical sequence among those showing
47 initial hemodynamic changes (abnormal UA PI or MCA PI values), the
48 frequency of fetuses following the classical sequence among those showing
49 late hemodynamic changes (an abnormal DV PIV value) and finally, the
50
51
52
53
54
55
56
57
58
59
60

1
2
3 frequency of cases with an abnormal DV PIV as the last parameter to be
4
5 affected among those with an abnormal DV PIV.
6

7
8 Subsequently, in order to compare how the three parameters became
9
10 abnormal in relation with the interval to delivery, we constructed three
11
12 scattergrams in which the differences between the 948 UA PI, MCA PI and
13
14 DV PIV values and their limit percentiles were plotted against the indicated
15
16 interval. In this graphs we drew a line that represented the limit centile for
17
18 each parameter (where the difference was equal to 0), and calculated three
19
20 regression lines for the scattered values representing the 10th, 50th and 90th
21
22 percentiles. All these regression lines were constructed using splines to allow
23
24 for non-linear relationships and taking into account that some of the values
25
26 might have been longitudinally obtained in the same patient. In order to
27
28 compare the three parameters, the x-axis point where the median regression
29
30 line crossed the limit centile line represented for each parameter the interval
31
32 to delivery in which 50% of the fetuses became abnormal. These crossing
33
34 points were used to compare the intervals among the three parameters.
35
36

37
38 Finally, a graph describing the cumulative sum of abnormal Doppler events in
39
40 the 948 examinations was plotted against the interval to delivery. Three
41
42 ascending lines representing the three Doppler parameters reflected how the
43
44 sum of abnormal Doppler examinations grew in relation to this interval.
45
46

47
48 The work received an IRB authorization to perform retrospective studies.
49
50 Statistical analysis and graphs were performed with R-Software® 3.2.2
51
52 (<http://www.r-project.org/>). The statistical significance was established at
53
54 $p < 0.05$. A search in PubMed was done, to identify previous citations reporting

RESULTS

The total number of examinations was 948, the total number of fetuses was 405 and the median (and interquartile range, IQR) GA at the first examination was 28.86 (27.14-31.43) weeks. All fetuses had at least one examination. Of these 157 (43.7%), 89 (24.8%), 42 (11.7%), 26 (7.2%), 13 (3.6%), 11 (3.1%), 7 (2.0%), 5 (1.4%), 4 (1.1%), 1 (0.3%), 3 (0.8%) and 1 (0.3%) were respectively examined 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, and 16 times.

The descriptive statistics of the study population are shown in table 1. The study group had a median (and IQR) maternal age of 30 (26-34) years a median GA at examination of 29.57 (28.14-31.71) weeks, a median GA at delivery of 31.79 (29.57-34) weeks, a median estimated fetal weight (EFW, according to Hadlock equation-4¹²) of 890 (640-1230) g, a median BW of 1080 (750-1380) g, a median EFW¹² centile of 0.09 (0.01-0.57), a median BW centile of 0.35 (0.08-1.42) and a median interval examination-delivery of 1.28 (0.43-2.89) weeks.

The order in which the abnormal Doppler values were observed and the frequency of the sequences of Doppler progression is shown in table 2 and in figure 1. Of the 405 fetuses studied, 46 (11.4%) did not present abnormal Doppler values, while 359 (88.6%) showed at least one abnormal Doppler value in any of the examinations performed. Of the 359 fetuses that presented Doppler anomalies, the most frequent sequence for the appearance of abnormal Doppler values (n=151, 42.1%) was that in which only the UA PI was abnormal, the second (n=87, 24.2%) in which an abnormal UA PI appeared first, followed by an abnormal MCA PI and the third (n=26, 7.2%) in which an abnormal MCA PI appeared first followed by an abnormal UA PI. Of

1
2
3 the 359 fetuses with any abnormal Doppler, 256 (71.3%) presented
4 progression orders that followed the classical sequence UA→MCA→DV,
5 while 103 (28.7%) did not. However, if we performed the analysis considering
6 the existence of early (changes in the UA and MCA PI) or late hemodynamic
7 changes (changes in the DV PIV), we found that those with early changes
8 (n=283) followed the classical sequence in a higher proportion of cases (n=
9 238, 84.1%). Conversely, when the DV was affected (n=73), the classical
10 sequence was much less frequent, and although in 64.4% (n=47) of these
11 fetuses the DV PI remained as the last parameter to be abnormal, only a
12 small proportion (n=18; 24.7%) of abnormal DV PIV values were preceded by
13 the full expected progression sequence.

21
22
23
24
25
26
27 Regarding the intervals to delivery, the percentile regressions drawn on the
28 scattergrams which represented the differences between the Doppler values
29 and the abnormal percentiles, showed that the UA PI was the first parameter
30 to be affected, as 50% of the fetuses (represented by the median line or
31 percentile 50th regression line) showed abnormal UA PI values 9 weeks
32 prior to delivery (figure 2A), while for the MCA PI this occurred 1 week before
33 delivery (figure 2B) and for the DV PIV 0 days before delivery (figure 2C).

34
35
36
37
38
39
40
41
42
43 Finally, the graph describing the cumulative sum of abnormal Doppler events
44 (figure 3) showed that the number of Doppler examinations crossing the limit
45 percentile raised in the UA PI 8 weeks prior to delivery, while in the MCA and
46 DV this was observed 3 weeks and one week before delivery, respectively

The literature review revealed 8 studies in which the sequence of Doppler
changes in pregnancies complicated by FGR was described. The details of
these studies are shown in table 3.

DISCUSSION

Summary of findings

The findings of this study suggest that the order of progression of Doppler abnormalities in early-onset SGA follows a predictable pattern in the majority of cases. The hemodynamic changes start with an increase in the UA PI, followed by a reduction in the MCA PI, and an increase in the DV PIV. In 71.3% of cases the observed pattern fully coincides with the previously reported order, and this frequency rises to 84.1% if we consider the early hemodynamic changes (abnormal UA PI and MCA PI) only. Furthermore the Doppler changes in the UA are already seen in 50% of the patients 9 weeks before delivery. This was followed by Doppler changes in the MCA PI and DV, which were observed in 50% of the pregnancies one and 0 weeks prior delivery, respectively.

Interpretation of these findings and comparison with existing literature

The initially described hemodynamic changes in early-onset SGA fetuses follow a pattern in which an early increase in the umbilical artery resistance, is followed by a mechanism of brain sparing with vasodilation of the MCA, and a further increase in the resistance in the DV, heralding the presence of brain sparing and cardiac failure⁴⁻¹⁰. This sequence of Doppler activations was recently challenged¹¹ suggesting that no specific order predominated over the other. We have shown that in contrary to these last descriptions, the order of progression of Doppler abnormalities during FGR tends to follow a predictable order that coincides with the physiological order of experimental adaption to growth restriction¹⁷.

1
2
3 Our study is in line with the earlier studies, reporting a common pattern of
4 Doppler progression⁴⁻¹⁰, and differs from the conclusions shown in the
5 PORTO study¹¹ (Table 3). An explanation could be the different inclusion
6 criteria in these studies. Our study included only pregnancies with suspected
7 early-onset SGA (defined as EFW below the 10th centile), which was
8 confirmed to be SGA at birth (defined as BW below the 10th centile).
9 Furthermore, our fetuses were examined before 34 weeks and were delivered
10 always before 37 weeks' gestation. Contrarily, the PORTO study included a
11 mix of pregnancies with early and late-onset cases, which according to their
12 data were frequently examined after 34 weeks and usually delivered after 37
13 weeks' gestation. This issue is of paramount importance, as the progression
14 of Doppler changes is known to differ in both gestational intervals according to
15 the different physiopathological mechanisms occurring in early and late-onset
16 FGR¹⁸.

33 34 Clinical and research implications

35
36 Taking into account that the late stages in the sequence of Doppler
37 deterioration are associated with a worse pregnancy outcome^{6,7}, the
38 existence of this predictable progression is crucial to schedule the frequency
39 of the ultrasound assessments and plan parental counselling¹⁹. Although the
40 aim of the study was the evaluation of the order of progression of Doppler
41 abnormalities, we also included a mean interval value for comparison
42 purposes among the three vessels and a cumulative sum of first time Doppler
43 abnormalities. Interestingly, our results were in line with the findings of
44 previous studies, especially those which aimed to calculate these intervals
45 and cumulative sums in a more accurate way^{4,20, 21}.

1
2
3 Two other interesting findings could also be highlighted in our study. One is
4 that the presence of an abnormal MCA PI occurs on average much later than
5 earlier described²⁰, when the UA impedance is already abnormal, a finding in
6 line with an earlier work published by our group²². The other is that the
7 expected sequence of Doppler progression seems to vary depending on the
8 stage of hemodynamic compensation. In fact, fetuses affected with early
9 Doppler changes (UA PI or MCA PI) tend to maintain more frequently the
10 predicted classical sequence (84.1%) than those at the end of the
11 hemodynamic compensation (abnormal DV PIV) (24.7%). Considering that
12 the presence of an abnormal DV has proven to be the best Doppler predictor
13 of fetal acidosis, and postnatal neurocognitive impairment²³⁻²⁴, our study
14 underlines that an abnormal DV PIV might not be always preceded by an
15 abnormal UA PI followed by an abnormal MCA PI, and could be, for example,
16 directly preceded by an abnormal UA PI without the presence of an abnormal
17 MCA PI (N=21, 5.8%). This issue is however minimized by the fact that 47
18 (64.4%) of the 73 cases with an abnormal DV Doppler, presented it as the last
19 parameter to be affected, and therefore the presence of an abnormal DV PI
20 should still be considered as a sign of late hemodynamic dysfunction.

43 Strengths and weaknesses

44
45 Our study is the first to study Doppler progression from a double perspective;
46 the order of appearance of Doppler abnormalities regardless of GA and time
47 intervals, and the analysis of Doppler abnormalities in relation to the
48 examination-to-delivery interval. We consider that this combined approach
49 provided more robust assessment in order to evaluate the progression of fetal
50 hemodynamics. Furthermore, our study focused on early-onset smallness by
51
52
53
54
55
56
57
58
59
60

1
2
3 including pregnancies with EFW less than 10th centile before 34 weeks'
4 gestation. However, we did not include other Doppler parameters such as the
5 aortic isthmus or the myocardial performance index^{20,21}. Unfortunately, these
6 data were not available in the majority of the cases. Also, we defined the
7 existence of an abnormal Doppler value when it was found abnormal for the
8 first time, even though it became normal afterwards in the follow-up, a
9 discrepancy that could be due to the use of corticosteroids for lung maturation,
10 which is known to influence the Doppler values²⁴ or directly due to technical or
11 intra and inter-observer measurement errors. We recognize that this might
12 cause biases in the calculation of frequencies and sequences of Doppler
13 abnormalities. However, the fact that all the parameters (UA, MCA and DV)
14 were affected similarly by the same circumstances would diminish the
15 possibility of systematic bias. Finally, considering the order of Doppler
16 progression, we considered that a parameter was affected first when
17 statistically its value was further away from the limit percentile. We were
18 aware that this was only a mathematical approach. However the bias was
19 again minimized considering that the possible error would be equally
20 distributed among the three parameters. In addition, from a methodological
21 point of view, it was the only way to analyze much of the data, as not
22 infrequently two different parameters were found to be affected at unison in
23 the same examination.

24 Conclusion

25 As observed in earlier animal experimentation¹⁷ and in earlier human
26 observational studies⁴⁻⁹, the progression order of Doppler abnormalities in
27 early-onset smallness tends to follow a predictable order, with an increase in

Figure 1. Sequence of progression for Doppler anomalies observed in the studied group of small-for-gestational age fetuses. 71% of cases coincided with the progressive sequence of abnormal values in the UA PI, MCA PI and DV PIV. Exceptions to this scenario occur mostly in the last stages of the hemodynamic progression.

Figure 3. Cumulative sum of Doppler anomalies along the interval to delivery. The UA was the parameter in which the abnormal percentile was sooner and most frequently crossed, followed by the MCA and the DV. The increase of Doppler examinations crossing the limit percentile appeared in the UA PI as soon as 8 weeks prior to delivery, while in the MCA and DV this was respectively observed 3 and 1 weeks before the end of pregnancy.

figure 3

Table 1.

Description of the study group

Parameter	Median (IQR) or N (%)
Age (years)	30 (26-34)
Gestational age at examination (weeks)	29.57 (28.14-31.71)
Gestational age at delivery	31.79 (29.57- 34)
EFW (Hadlock-4) (grams)	890 (640 -1230)
BW (grams)	1080 (750-1380)
EFW (Hadlock-4) centile	0.09 (0.01-0.57)
BW centile	0.35 (0.08, 1.42)
Interval examination-delivery (weeks)	1.28 (0.43, 2.89)
Gestational age at the 1 st examination (weeks)	28.86 (27.14-31.43)
Examinations (total)	948
Fetuses (total)	405
Fetuses with no abnormal Doppler	46 (11.4%)
Fetuses with any abnormal Doppler	359 (88,6%)
Fetuses with 1 examination	157 (43.73)
Fetuses with 2 examinations	89 (24.79)
Fetuses with 3 examinations	42 (11.70)
Fetuses with 4 examinations	26 (7.24)
Fetuses with 5 examinations	13 (3.62)
Fetuses with 6 examinations	11 (3.06)
Fetuses with 7 examinations	7 (1.95)
Fetuses with 8 examinations	5 (1.39)
Fetuses with 9 examinations	4 (1.11)
Fetuses with 10 examinations	1 (0.28)
Fetuses with 11 examinations	3 (0.84)
Fetuses with 16 examinations	1 (0.28)

Table 2

Progression pattern for the Doppler anomalies in the UA, MCA and DV;
percentage of progression for the different sequences.

Sequence	N	Frequency
Total early-onset small fetuses (EFW<p10)	405	100.00%
No abnormal Doppler found in the follow-up	46	11.36%
Any abnormal Doppler found in the follow-up	359	88.64%
UA alone	151	42.06%*
UA→MCA	87	24.23%*
MCA→UA	26	7.24%*
UA→DV	21	5.84%*
MCA alone	19	5.29%*
UA→MCA→DV	18	5.01%*
UA→DV→MCA	15	4.17%*
DV→MCA	4	1.11%*
DV→UA	4	1.11%*
MCA→UA→DV	3	0.83%*
MCA→DV	3	0.83%*
DV alone	2	0.56%*
MCA→DV→UA	1	0.28%*
DV→UA→MCA	1	0.28%*
DV→MCA→UA	1	0.28%*
Sequences following the classical sequence among those with any abnormal Doppler (UA alone, UA→MCA, UA→MCA→DV)	256	71.31%*
Sequences not following the classical sequence among those with any abnormal Doppler (UA→DV, MCA alone, MCA→UA, UA→DV→MCA, DV alone, DV→MCA, DV→UA, MCA→UA→DV, MCA→DV, MCA→DV→UA, DV→UA→MCA, DV→MCA→UA)	103	28.69%*
Sequences following the classical sequence in early stages of hemodynamic dysfunction (abnormal Doppler in the UA or MCA, N=283). (UA alone, UA→MCA)	238	84.10% [†]
Sequences not following the classical sequence in early stages of hemodynamic dysfunction (abnormal Doppler in the UA or MCA, N=283). (MCA alone, MCA→UA)	45	15.90% [†]
Sequences following the classical sequence in late stages of hemodynamic compensation (abnormal Doppler in the DV, N=73). (UA→MCA→DV)	18	24.66% ^{††}
Sequences not following the classical sequence in late stages of hemodynamic compensation (abnormal Doppler in the DV, N=73). (UA→DV, UA→DV→MCA, DV alone, DV→MCA, DV→UA, MCA→UA→DV)	55	75.34% ^{††}

MCA→DV, MCA→DV→UA, DV→UA→MCA, DV→MCA→UA)		
DV PIV as the last abnormal Doppler to be affected in fetuses with an abnormal Doppler in the DV, (N=73).	47	64.38% ^{††}

Notes: UA=umbilical artery Doppler, MCA= middle cerebral artery Doppler, DV= ductus venosus Doppler, p=percentile, *indicated percentage refers only to cases with any abnormal Doppler (N=359), [†]indicated percentage refers only to early stages of hemodynamic dysfunction (abnormal Doppler in the UA or MCA) (N=283), ^{††}indicated percentage refers only to late stages of hemodynamic dysfunction (abnormal Doppler in the DV) (N=73), ^{††}indicated percentage refers only to fetuses with an abnormal Doppler in the DV (N=73).

Table 3

Comparison among the different studies evaluating either Doppler progression or the sequence of changes followed by the different Doppler parameters.

Study	N	GA at exam (weeks)	GA at delivery (weeks)	Inclusion criteria	Vessels examined	Other exams	Interval exam.	Number exams per fetus	Criteria for abnormal Doppler	Finalization of pregnancy criteria	Method of analysis	Conclusions
Ozcan et al ⁷ 1998	19 fetuses	26.4-31.4	27-32	EFW<P5 th	UA, MCA, DV, UV	CTG	No interval (1 measurement only)	1 (the last)	First measurement abnormal	Abnormal CTG	Association of arterial and venous Doppler parameters with perinatal outcome	DV Doppler was the only parameter associated with perinatal death and low 5 th Apgar score
Baschat et al ⁶ 2000	121 fetuses	Not indicated	24-40 G1: 27-40 G2: 27-37 G3: 24-37	AC<P5 th + abnormal UA PI. BW<P10 th	UA, MCA, DV, IVC, UV	CTG, BPS	Not indicated	At least 2	First measurement abnormal [†]	Abnormal CTG and BPS	Classification of fetuses in 3 groups according to Doppler findings with outcome comparison	Progression of Doppler changes exists: 1-UA, 2-MCA, 3-DV. Outcome depends on progression.
Baschat et al ⁵ 2001	236 fetuses 44 with abnormal BPS	16-37 Entry at: 16-31, Last exam: 24-37	25-37 (Stillbirth: 25-28, livebirths: 26-37)	AC<P5 th + abnormal UA PI. BW<P10 th	UA, MCA, DV, IVC, UV	CTG, BPS	1-14 days, daily the last week	4-17	First measurement abnormal [†]	Abnormal BPS, CTG	Percentage of abnormal Doppler findings. Frequencies for Doppler deterioration sequences, progression interval	UA-MCA-DV sequence occurs in 73% of cases. In 64% with the full sequence. BPS deteriorates at the end of the sequence.
Hecher et al ¹⁰ 2001	547 exams, 93 fetuses with at least 3 exams 24 h prior to delivery	24-40 Entry at: 24-34	24-40 Group 1 (24-31) Group 2 (32-40)	AC<P5 th	UA, DT-Ao, MCA, DV, IVC	CTG	1-7 days depending on Doppler findings	3-27 (At least 3)	First measurement abnormal	CTG, Attending obstetrician discretion	Patterns of progression: GA at onset, interval to delivery, progression intervals, classification in 2 groups with outcome comparison	Temporal sequence of changes exist: 1-UA, 2-MCA, 3-DV. Outcome depends on progression, DV and CTG are the best predictors of mortality
Ferrazzi et al ⁴ 2002	26 fetuses	<32-34 Entry <32 weeks, followed until 34 weeks	26-34	AC<P2 nd abnormal UA PI, abnormal Ut PI	UA, MCA, UtA, DV, Ao-OT, P-OT	CTG	2 per week	Not indicated	Two or more consecutive abnormal measurements	CTG, exclusion of pregnancies with maternal causes to finalize	Cumulative onset time curves of Doppler anomalies, interval to delivery. Outcome according to progression	Temporal sequence of changes exist: 1-UA and Ut, 2-MCA, 3-DV. Outcome depends on progression. Late changes are the best predictors of adverse outcome.
Uran et al ⁸ 2008	668 Doppler exams, 104 fetuses	23-33	26-40	AC<P5 th + abnormal UA PI or CPR. BW<P10 th	UA, MCA, CPR, DV, UV	CTG	1-56 days	3-26 (At least 3)	First measurement abnormal	CTG Attending obstetrician discretion	Patterns of progression: GA at onset, interval to delivery, progression intervals	According to the interval to delivery, a temporal sequence of changes exist: 1-UA, 2-MCA, 3-DV.
Interscheider et al (PORTO) ¹¹ 2013	7769 exams, 1116 patients	24-36 at first exam. Interval of exams not indicated	Not indicated Mean and SD 37.8 +3 weeks	EFW<P10 th	UA, MCA, DV, AoI, MPI	CTG	1-14 days	Not indicated	Not indicated	CTG, Attending obstetrician discretion	Frequencies for Doppler deterioration sequences, Cumulative Frequencies of Doppler anomalies, interval to delivery	Temporal sequence of changes like 1-UA, 2-MCA, 3-DV does not exist as other sequences present a similar frequency
Morales-Roselló et al	948 exams, 405 fetuses	24-33+6	<37	EFW<p10 th Suspicion of SGA Plus BW<p10 th	UA, MCA, DV	CTG		1-16	First measurement abnormal	CTG, Attending obstetrician discretion	Frequencies for Doppler deterioration sequences, Cumulative Frequencies of Doppler anomalies, interval to delivery	Temporal sequence of changes: 1-UA, 2-MCA, 3-DV exists. UA-MCA-DV sequence occurs in 2 thirds % of cases. Interval to delivery is shorter for the DV

NOTES: UA: umbilical artery, MCA: middle cerebral artery, DV: ductus venosus, UV: umbilical vein, MPI: myocardial performance index, AoI: aortic isthmus, DT-Ao: descending thoracic aorta, Ao-OT: aortic outflow tract, P-OT: pulmonary outflow tract, IVC: inferior vena cava, PI: pulsatility index, G: group, P: percentile, [†]cases with 2 normalized MCA PI values were excluded, exam: examination, EFW: estimated fetal weight, CTG: cardiotocogram, BPS: biophysical score, GA: gestational age.
