Supplementary methods

Estimation of explained heritability. Restricted maximum likelihood (REML) analysis using Fisher algorithm was implemented in GCTA64 to estimate the proportion of phenotypic variance explained by studied SNPs. Principal components (PCs) and country of origin were included as covariates to adjust for population structure and potential environmental confounders. This analysis was repeated excluding variants within the HLA region to explore the specific contribution of HLA and non-HLA loci to disease heritability.

Enrichment in epigenetic marks. To infer the possible biological function of the associated loci, we performed regulatory enrichment analysis including both the suggestive and significant SNPs. We used the tool GoShifter¹, which allows us to calculate the statistical enrichment in a set of SNPs given a functional annotation. Specifically, we tested functional annotations from the Roadmap Epigenomics Consortium², which includes a variety of histone marks related to active promoter regions (H3K9ac, H3K4me2, H3K4me3, H3K4ac), accessible or active genes (H3K79me1, H2BK15ac) and active enhancers (H3K27ac, H3K3me1, H2BK20ac). Only functional annotations from vascular and immune tissues or cell types were included.

Fine-mapping of associated loci. All non-HLA significant signals were fine-mapped using PAINTOR³ to perform an exhaustive analysis of the potential causality of associated SNPs. PAINTOR performs probabilistic inference and computes posterior probabilities (PP) for SNPs to be causal considering the strength of association (Z score) and the LD pattern across genomic regions. Additionally, PAINTOR leverages functional annotation data as a prior probability to improve SNP prioritisation. Finally, the method uses Bayes theorem to obtain PP for SNPs to be causal, which in turn are used to generate 95% credible sets (the smallest list of variants that jointly have a probability of including the causal variant $\geq 95\%$). For the PAINTOR fine-mapping we included any histone mark annotation that showed significant enrichment in the GoShifter analysis, as well as expression quantitative trait loci (eQTLs) and splicing quantitative trait loci (sQTL) data from immune and arterial tissues from GTEx⁴.

Functional annotation and gene prioritisation. To prioritise potential genes affected by the associated SNPs, we conducted gene mapping of the significant associations, using the SNP2GENE function from FUMA⁵. Only those SNPs included in the previously established credible sets were considered. This tool uses a collection of epigenomic and transcriptomic databases to evaluate the implication of the SNPs on the regulation of potential causal genes, or their physical chromatin interaction with a specific gene. FUMA parameters are shown in the appendix (p 14). We also evaluated complementary information from Open Target Genetics⁶. We considered items from three main categories: the physical position of the variant regarding the proposed gene, reported effects of the variant over the expression of the proposed gene or protein, and reported chromatin interaction between the SNP and the proposed gene. These considered items are displayed in the appendix (p 15). Only coding genes and those genes scoring at least once in any category were considered candidate genes.

Drug repurposing. Drug repurposing was conducted to propose potential new treatment options for GCA. For this analysis, we included those candidate genes prioritised from the gene mapping analysis. Moreover, to identify genes interacting with the proposed genes, we calculated the protein-protein interaction (PPI) network using STRING⁷, with a minimum required interaction score of 0.70 (high confidence) and excluding "text mining" as a source of interaction prediction. We then searched the DrugBank⁸ database for therapies targeting any of these genes. To propose potential treatments for GCA, we focused on the mechanism of action of the different drugs as reported in DrugBank and we also performed a manual literature search.

Genetic risk prediction. We defined a polygenic risk score (PRS) to predict the genetic predisposition of an individual to develop GCA. First, we split the genomic data into a training set (9 cohorts; 2,464 cases and 14,256 controls), which was used to develop the prediction model, and a test set (Spanish cohort; 1,034 cases and 1,294 controls) to evaluate the prediction ability of the model. Based on the association results considering the training set, we extracted the suggestive and significant SNPs to develop a PRS. First, we conducted a clumping analysis on these variants to identify groups of linked SNPs ($r^2>0.2$). Subsequently, only independent SNPs were included in the models. We used the score function of PLINK v1.90 to calculate the number of

effect alleles per individual, each weighted by the logarithm of the OR. To avoid an overestimation of the weight of the HLA association, only the HLA variants identified as independent in our conditional analysis were included in the model. Additionally, we tested sex as a possible covariate of the model. After developing the PRS using the data of the training set, we calculated the prediction ability of the model on the test set, defining the predictor area-under-the-curve (AUC) using the pROC R package⁹. Furthermore, we assessed the capability of the model to identify high-risk individuals by setting various risk percentile thresholds and examining the statistical significance of each division through a χ^2 test.

Supplementary figures

Supplementary Figure 1

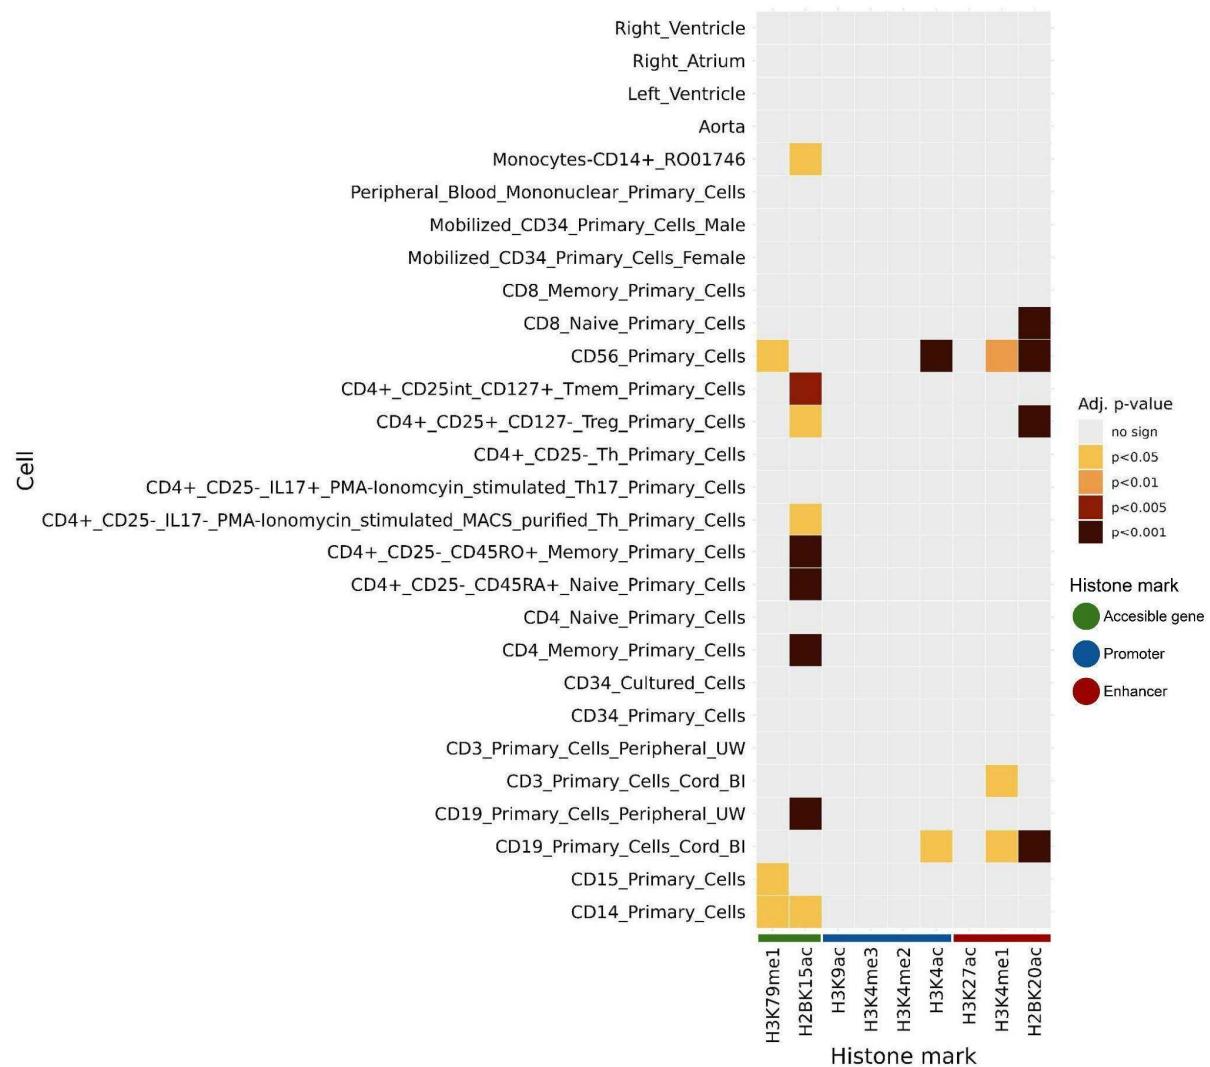

Manhattan plot of the GWAS results. The $-\log_{10}$ of the inverse variance weighted meta-analyses p values are plotted against their physical chromosomal position. The red line represents the significant level of association ($p < 5 \times 10^{-8}$) while the blue line represents the suggestive level ($p < 5 \times 10^{-5}$). *Associations not previously described.

Supplementary Figure 2

Regional plot of the imputed HLA variants. On the top, the association results before conditional analysis are shown. The five independent variants, determined by the conditional analysis, are highlighted. On the bottom, the association results after conditioning for the five independent variants. The variant type is marked by colour and the red line marks the established significant threshold ($p < 1 \times 10^{-6}$).

Supplementary Figure 3

Tile plot of the histone mark enrichment analysis for immune cell types and vascular tissues from the ROADMAP database. The significance of the enrichment (adjusted p-value) is represented by the tile colour, while the colour on the horizontal axis indicates histone marks associated with accessible genes (green), promoters (blue), and enhancers (red).

Supplementary Table 5. Items considered for causal gene prioritisation

Item name	Disclosed definition	Data source
Within gene body	Any credible set SNP is located within the genomic position of the proposed gene	FUMA
Missense variant	Any credible set SNP is a missense variant for the proposed gene	FUMA
Physically near	The lead SNP is physically close (10kb max) to the proposed gene	FUMA
Blood eQTL	Any credible set SNP is a reported eQTL for any whole-blood sample	FUMA
Immune cell eQTL	Any credible set SNP is a reported eQTL for any immune cell-specific annotation	FUMA
Vascular tissue eQTL	Any credible set SNP is a reported eQTL for any vascular tissue annotation	FUMA
pQTL	The lead SNP is a reported pQTL for the proposed gene	Open Targets Genetics
Chromatin interaction	Any credible set SNP has chromatin interaction evidence for 3D physical interaction between the SNP region and the proposed gene region	FUMA
Highest V2G Score	Highest Variant-to-Gene score from Open Targets Genetics for the lead SNP-proposed gene pairs. All values are displayed when available	Open Targets Genetics

SNP, single nucleotide polymorphism; OR, odds ratio; CI, confidence interval
Only significant p-values are shown. P-values were adjusted when the Cochran's Q was significant.

Supplementary Table 7. Lead variants showing genome-wide significant association with GCA after meta-analysis.

SNP, single nucleotide polymorphism; OR, odds ratio; CI, confidence interval

Only suggestive and significant p-values are shown. P-values were adjusted when the Cochran's Q was significant.
