## ABSTRACT

### Background

Intestinal dysbiosis may contribute to the pathogenesis of necrotising enterocolitis (NEC) in very preterm or very low birth weight (VLBW) infants. Dietary supplementation with synbiotics (probiotic micro-organisms combined with prebiotic oligosaccharides) to modulate the intestinal microbiome has been proposed as a strategy to reduce the risk of NEC and associated mortality and morbidity.

### Objectives

To assess the effect of enteral supplementation with synbiotics (versus placebo or no treatment, or versus probiotics or prebiotics alone) for preventing NEC and associated morbidity and mortality in very preterm or VLBW infants.

### Search methods

We searched the Cochrane Central Register of Controlled Trials, MEDLINE, Embase, the Maternity and Infant Care database and CINAHL, from earliest records to 17 June 2021. We searched clinical trials databases and conference proceedings, and examined the reference lists of retrieved articles.

### Selection criteria

We included randomised controlled trials (RCTs) and quasi-RCTs comparing prophylactic synbiotics supplementation with placebo or no synbiotics in very preterm (< 32 weeks' gestation) or very low birth weight (< 1500 g) infants.

### Data collection and analysis

Two review authors separately performed the screening and selection process, evaluated risk of bias of the trials, extracted data, and synthesised effect estimates using risk ratio (RR), risk difference (RD), and mean difference, with associated 95% confidence intervals (CIs). We used the GRADE approach to assess the level of certainty for effects on NEC, all-cause mortality, late-onset invasive infection, and neurodevelopmental impairment.

### Main results

We included six trials in which a total of 925 infants participated. Most trials were small (median sample size 200). Lack of clarity on methods used to conceal allocation and mask caregivers or investigators were potential sources of bias in four of the trials. The studied synbiotics preparations contained lactobacilli or bifidobacteria (or both) combined with fructo- or galacto-oligosaccharides (or both).

Meta-analyses suggested that synbiotics may reduce the risk of NEC (RR 0.18, 95% CI 0.09 to 0.40; RD 70 fewer per 1000, 95% CI 100 fewer to 40 fewer; number needed to treat for an additional beneficial outcome (NNTB) 14, 95% CI 10 to 25; six trials (907 infants); low certainty

evidence); and all-cause mortality prior to hospital discharge (RR 0.53, 95% CI 0.33 to 0.85; RD 50 fewer per 1000, 95% CI 120 fewer to 100 fewer; NNTB 20, 95% CI 8 to 100; six trials (925 infants); low-certainty evidence). Synbiotics may have little or no effect on late-onset invasive infection, but the evidence is very uncertain (RR 0.84, 95% CI 0.58 to 1.21; RD 20 fewer per 1000, 95% CI 70 fewer to 30 more; five trials (707 infants); very low-certainty evidence). None of the trials assessed neurodevelopmental outcomes. In the absence of high levels of heterogeneity, we did not undertake any subgroup analysis (including the type of feeding).

### Authors' conclusions

The available trial data provide only low-certainty evidence about the effects of synbiotics on the risk of NEC and associated morbidity and mortality for very preterm or very low birth weight infants. Our confidence in the effect estimates is limited; the true effects may be substantially different from these estimates. Large, high-quality trials would be needed to provide evidence of sufficient validity and applicability to inform policy and practice.

## PLAIN LANGUAGE SUMMARY

### Do synbiotics prevent necrotising enterocolitis in very preterm or very low birth weight infants?

#### Background

Very preterm (born more than eight weeks early) and very low birth weight (less than 1.5 kg) infants are at risk of developing necrotising enterocolitis, a severe condition where some of the lining of the infant's bowel becomes inflamed, and the cells of this tissue die. This condition is associated with death, serious infection, and long-term disability, as well as developmental problems.

#### What did we want to find out?

One way to help prevent necrotising enterocolitis may be to add synbiotics (combinations of probiotic bacteria or yeasts plus non-digestible sugars to support probiotic growth and colonisation) to milk feeds. We wanted to find out whether synbiotics might benefit very preterm and very low birth weight infants. Our outcomes of interest included necrotising enterocolitis, death from any cause, serious infection, duration of hospitalisation since birth and neurodevelopmental outcomes.

#### What did we do?

For our Cochrane Review, we searched several important databases to identify randomized controlled trials that investigated the use of synbiotics for preventing necrotising enterocolitis in very preterm and very low birth weight infants. We used standard Cochrane methods to conduct our review and perform our analyses. We used the GRADE approach to assess the certainty of the evidence for each outcome.

#### What did we find?

We found six trials with a total of 925 infant participants. Trials were mostly small, and most had design flaws that might have biased their findings.

#### Main results

Combined analyses showed that giving synbiotics to very preterm or very low birth weight infants may reduce the risk of necrotising enterocolitis and death. Synbiotics may have little or no effect in reducing the risk of serious infection, but the evidence is very uncertain. None of the studies that we identified assessed the effect of synbiotics on disability or developmental outcomes.

#### What are the limitations of this evidence?

Although the evidence from randomised controlled trials can potentially be of high certainty, the methods used in our review's included trials may have introduced biases that exaggerated the benefits of giving synbiotics to very preterm and very low birth weight infants. Also, because most of the trials were small, the effect estimates for some outcomes were imprecise. For these reasons, we graded down the certainty of the evidence. All evidence in our review is of low or very low certainty.

There is low-certainty evidence that synbiotics prevent necrotising enterocolitis and death from any cause. There is very low-certainty evidence that synbiotics may have little or no effect in preventing serious infection.

#### How up to date is this evidence?

We conducted our database searches on 17 June 2021.

## SUMMARY OF FINDINGS

### Summary of findings 1. Synbiotics compared to control in very preterm or very low birth weight infants

#### Synbiotics compared to control in very preterm or very low birth weight infants

**Patient or population:** very preterm or very low birth weight infants

**Setting:** neonatal care centres globally

**Intervention:** synbiotics (typically *Bifidobacterium spp.*, *Lactobacillus spp.*, plus fructo- or galacto-oligosaccharides (or both))

**Comparison:** control

Outcomes	Anticipated absolute effects* (95% CI)		Risk ratio (95% CI)	Absolute effect (95% CI)	N° of participants (studies)	Certainty of the evidence (GRADE)
	Risk with control	Risk with Probiotics				
Necrotising enterocolitis (before hospital discharge)	83 per 1000	15 per 1000 (7 to 33)	0.18 (0.09 to 0.40)	70 per 1000 fewer (100 fewer to 40 fewer per 1000)	907 (6 studies)	⊕⊕⊕⊕ Low <sup>a</sup>
Mortality (all-cause before hospital discharge)	93 per 1000	50 per 1000 (31 to 79)	0.53 (0.33 to 0.85)	50 per 1000 fewer (120 fewer to 100 fewer per 1000)	925 (6 studies)	⊕⊕⊕⊕ Low,b,c
Late-onset Invasive infection (before hospital discharge)	134 per 1000	113 per 1000 (78 to 162)	0.84 (0.58 to 1.21)	20 per 1000 fewer (70 fewer to 30 more per 1000)	707 (5 studies)	⊕⊕⊕⊕ Very low <sup>c,d</sup>
Neurodevelopmental impairment (assessed beyond infancy)	None of the included trials reported neurodevelopmental outcomes.					

\*The risk in the intervention group (and its 95% confidence interval (CI) is based on the assumed risk in the comparison group and the **relative effect** of the intervention and its 95% CI.

#### GRADE Working Group grades of evidence

**High certainty:** we are very confident that the true effect lies close to that of the estimate of the effect.

**Moderate certainty:** we are moderately confident in the effect estimate; the true effect is likely to be close to the estimate of the effect, but there is a possibility that it is substantially different.

**Low certainty:** our confidence in the effect estimate is limited; the true effect may be substantially different from the estimate of the effect.

**Very low certainty:** we have very little confidence in the effect estimate; the true effect is likely to be substantially different from the estimate of effect.

<sup>a</sup> Methodological limitations in trials (high risk of bias due to uncertainty about methods used to generate random sequence, conceal allocation, and mask outcome assessment); downgraded two levels for NEC because of subjectivity in ascertainment and diagnosis.

- b* Methodological limitations in trials (high risk of bias due to uncertainty about methods used to generate random sequence, conceal allocation, and mask outcome assessment):  
downgraded one level for all-cause mortality before discharge because of objectivity in ascertainment and diagnosis.
- c* Serious imprecision of effect estimate (low number of events).
- d* Methodological limitations in trials (high risk of bias due to uncertainty about methods used to generate random sequence, conceal allocation, and mask outcome assessment):  
downgraded two levels for late-onset invasive infection because of subjectivity in ascertainment and diagnosis.

## BACKGROUND

This review assesses the randomised controlled trial (RCT) evidence for the effect of enteral synbiotics (combinations of probiotic micro-organisms and prebiotic oligosaccharides) for preventing necrotising enterocolitis (NEC) in very preterm or very low birth weight (VLBW) infants. Other Cochrane Reviews assess the evidence for probiotics alone (Sharif 2020) or prebiotics alone (Sharif 2021a).

### Description of the condition

Necrotising enterocolitis is a syndrome of acute intestinal necrosis that affects about one in twenty very preterm (< 32 weeks' gestation) or VLBW (< 1500 g) infants (Horbar 2012). The risk factors for NEC include being extremely preterm (< 28 weeks' gestation) or extremely low birth weight (ELBW) (< 1000 g), and intrauterine growth restriction or compromise indicated by absent or reversed end-diastolic flow velocities in antenatal Doppler studies of the umbilical artery or fetal aorta (Samuels 2017). Infants who develop NEC experience more infections, have lower levels of nutrient intake, grow more slowly, and have longer durations of intensive care and hospital stay than gestation-comparable infants who do not (Battersby 2018; Berrington 2012). The mortality rate of infants with NEC is about 20%. Compared with their peers, infants who survive NEC have a higher risk of neurodevelopmental problems and disability, especially if it is associated with bloodstream infections (Hickey 2018).

The pathogenesis of NEC is not fully understood but is postulated to involve intestinal dysbiosis, infection and inflammation (Eaton 2017; Mara 2018; Stewart 2016). Evidence exists that the pattern, diversity and stability of the intestinal microbiome is associated with the risk of developing NEC (Masi 2019; Olm 2019; Stewart 2012; Warner 2016). Compared with cow milk formula, feeding with human milk reduces the risk of NEC in very preterm or VLBW infants (Quigley 2019). A putative mechanism for this protective effect is that prebiotic human milk oligosaccharides promote the growth of non-pathogenic probiotic micro-organisms, such as lactobacilli and bifidobacteria, which modulate the intestinal microbiome and promote mucosal barrier functions (Embleton 2017; Granger 2020; Walsh 2019). Compared with human milk-fed term infants, however, very preterm or VLBW infants tend to harbour fewer intestinal probiotic micro-organisms, and more potential pathogens, which might be due to dysbiotic effects of enteral fasting and antibiotic exposure (Stewart 2017).

### Description of the intervention

#### Synbiotics (probiotic-prebiotic combinations)

Synbiotics are combinations of probiotics and prebiotics. The prebiotic content is intended to enhance probiotic growth and intestinal colonisation (Nolan 2020).

#### Probiotics

Probiotics are live micro-organisms (predominantly bifidobacteria and lactobacilli) that benefit the host by modulating the intestinal microbiome and promoting mucosal barrier functions and resistance to pathogens (Berrington 2019; Esaiassen 2018). Preterm infants supplemented enterally with bifidobacteria and lactobacilli establish an intestinal microbiome that is dominated by probiotics and contains fewer potential pathogens, compared

with non-supplemented infants (Alcon-Giner 2020). Meta-analysis of data from more than 50 RCTs using a variety of probiotic strains and multi-organism combinations suggests that in very preterm or VLBW infants, probiotic supplementation may reduce the risk of NEC, and probably reduces all-cause mortality before hospital discharge as well as late-onset invasive infection (Sharif 2020). The certainty of this evidence is low, however, because of concerns that effect estimates are inflated by methodological weaknesses in the trials, which were mainly small, and by publication bias. Consequently, and because of ongoing issues about safety and the availability of regulated products, probiotic supplementation has not become established as a common practice in most neonatal care facilities (Duffield 2019; Fleming 2019; Pell 2019; Vermeulen 2020).

#### Prebiotics

Prebiotics are a diverse family of complex glycans that promote intestinal colonisation with probiotic micro-organisms. Human milk contains numerous prebiotic substances, predominantly galacto-oligosaccharides and fructo-oligosaccharides, which influence the intestinal microbiome in preterm infants (Boehm 2008; Nolan 2020). Natural human milk oligosaccharides vary markedly between individual women, and vary temporally (depending on the stage of lactation) within individual women (Aakko 2017; Smilowitz 2013). Newborn infants do not digest human milk oligosaccharides. Rather, these are primarily nutrient sources for intestinal probiotic micro-organisms, particularly bifidobacteria (Alcon-Giner 2020; Jost 2015). Feeding with human milk, rather than cow milk-derived formula, may reduce intestinal dysbiosis, and there is emerging evidence about how specific human milk oligosaccharides promote probiotic predominance in very preterm infants (Lyons 2020; Masi 2020; Underwood 2015).

Manufactured or plant-based (e.g. inulin) prebiotic oligosaccharides are less heterogeneous than natural human milk oligosaccharides, and typically consist of short chains of galactose or fructose, usually with a terminal glucose monomer (Johnson-Henry 2016). Evidence exists that giving supplemental synthetic prebiotic oligosaccharides to formula-fed very preterm infants stimulates the growth of an intestinal microflora that is similar to that found in infants fed with maternal milk (Autran 2018; Boehm 2008; Kapiki 2007; Veereman-Wauters 2011). RCTs have not, however, provided evidence of their effectiveness in preventing NEC, NEC-associated morbidity or all-cause mortality before hospital discharge (Chi 2019; Johnson-Henry 2016; Srinivasjois 2013).

### How the intervention might work

It is postulated that administering supplemental prebiotic oligosaccharides enhances both exogenous and endogenous probiotic growth and intestinal colonisation (Nolan 2020; Underwood 2019). Probiotic bacteria and fungi use prebiotic oligosaccharides as a major nutrient source (Alcon-Giner 2020). Bifidobacteria and lactobacilli ferment prebiotic oligosaccharides to produce short-chain fatty acids that inhibit adhesion of pathogenic bacteria and modulate intestinal epithelial integrity and barrier function (Johnson-Henry 2016). Synbiotic combinations, therefore, may be more effective than supplementation with either a probiotic or prebiotic alone (Zmora 2018). A recent RCT involving more than 4500

newborn infants (birth weight at least 2000 grams or gestation greater than 34 weeks) in rural India showed that enteral synbiotic supplementation (*Lactobacillus plantarum* plus fructo-oligosaccharide) was associated with a reduced risk of neonatal sepsis (Panigrahi 2017).

### Why it is important to do this review

Necrotising enterocolitis and associated complications, particularly infection, are the most common causes of mortality and serious morbidity in very preterm or VLBW infants beyond the early neonatal period (Berrington 2012). A 2019 Cochrane Review found only low-certainty evidence that probiotic or prebiotic supplementation alone reduce the risk of NEC (Quigley 2019). Given the plausibility that synbiotics might have an advantage over probiotics or prebiotics alone, appraising and synthesising the trial evidence about the benefits and harms of synbiotics supplementation could inform practice, policy and research.

## OBJECTIVES

To assess the effect of enteral supplementation with synbiotics (versus placebo or no treatment, or versus probiotics or prebiotics alone) for preventing NEC and associated morbidity and mortality in very preterm or VLBW infants.

## METHODS

### Criteria for considering studies for this review

#### Types of studies

Randomised or quasi-randomised (predictable allocation) controlled trials, including cluster-RCTs.

Cross-over studies were not eligible for inclusion.

#### Types of participants

Very preterm (< 32 weeks' gestation) or VLBW (< 1500 g) infants.

#### Types of interventions

Prophylactic enteral synbiotics: any combination or dose of probiotic organisms and prebiotic oligosaccharides, commenced within 14 days of birth and continued daily (or more frequently) for at least one week. Probiotics and prebiotics need not be given simultaneously, but should be given on the same day.

#### Types of outcome measures

We focused on assessing effects on infant- and family-important outcomes, principally neonatal morbidities that plausibly affect rates of mortality or neurodisability. We did not include surrogate outcomes such as stool colonisation patterns.

#### Primary outcomes

- NEC before discharge from hospital, confirmed at surgery or autopsy or using standardized clinical and radiological criteria (VON 2020):
  - at least one of: bilious gastric aspirate or emesis; or abdominal distention; or blood in stool; and
  - at least one of: abdominal radiograph showing pneumatosis intestinalis; or gas in the portal venous system; or free air in the abdomen

- All-cause mortality before discharge from hospital

#### Secondary outcomes

- Late-onset invasive infection, as determined by the culture of bacteria or fungus from blood or cerebrospinal fluid or from a normally sterile body space (> 48 hours after birth until discharge from hospital)
- Invasive infection with the supplemented probiotic micro-organism until discharge from hospital
- Duration of hospitalisation since birth
- Neurodevelopmental impairment assessed by a validated test after 12 months' post-term: neurological evaluations, developmental scores, and classifications of disability, including cerebral palsy and auditory and visual impairment

### Search methods for identification of studies

We used the criteria and standard methods of Cochrane Neonatal.

#### Electronic searches

We searched the Cochrane Central Register of Controlled Trials (CENTRAL; 2021, Issue 6) in the Cochrane Library; MEDLINE Ovid (1946 to June 2020), Embase Ovid (1974 to June 2021), Maternity and Infant Care Database Ovid (1971 to May 2021), the Cumulative Index to Nursing and Allied Health Literature (CINAHL) (1982 to June 2021) using a combination of text words and Medical Subject Heading (MeSH) indexing terms described in Appendix 1. We limited the search outputs with filters for clinical trials as recommended in the *Cochrane Handbook for Systematic Reviews of Interventions* (Higgins 2020). We did not apply any language restrictions.

We searched for ongoing or recently completed trials at the US National Institutes of Health's trials registry ([clinicaltrials.gov](http://clinicaltrials.gov)), the World Health Organization's International Clinical Trials Registry Platform ([trialsearch.who.int](http://trialsearch.who.int)), and the ISRCTN Registry ([www.isrctn.com](http://www.isrctn.com)).

#### Searching other resources

We examined the reference lists of any articles selected for inclusion in this review.

### Data collection and analysis

We used the standard methods of Cochrane Neonatal.

#### Selection of studies

Two review authors (SS, PTH or SO) independently screened the titles and abstract of all studies and assessed full-text articles for all potentially relevant trials. We excluded those reports that did not meet all of the inclusion criteria, and we stated the reasons for exclusion. We discussed disagreements until consensus was achieved, with referral to another review author (WM) for final decision as necessary.

#### Data extraction and management

Two review authors (SS, SO or WM) extracted data independently, using a form to aid extraction of information on design, methodology, participants, interventions, outcomes and treatment effects from each included study. We discussed disagreements until we reached a consensus. If data from the study reports

were insufficient, we contacted the report authors for further information.

### Assessment of risk of bias in included studies

Two review authors (SS, SO or WM) independently assessed the risk of bias (low, high or unclear) of all included trials using the original version of Cochrane's 'Risk of bias' tool (Higgins 2011). We assessed the following domains:

- sequence generation (selection bias);
- allocation concealment (selection bias);
- blinding of participants and personnel (performance bias);
- blinding of outcome assessment (detection bias);
- incomplete outcome data (attrition bias);
- selective reporting (reporting bias);
- any other bias (including baseline imbalance).

Had any disagreements occurred, we planned to resolve these through discussion or by involving the third review author. See Appendix 2 for a description of risk of bias for each domain.

For cluster-RCTs, where groups of individuals were randomized to the different interventions, we additionally planned to assess bias arising from prior knowledge of cluster-allocation (identification/recruitment bias, suggested by baseline imbalances in characteristics of participants rather than of clusters) and bias arising from the timing of identification and recruitment of participants (Higgins 2020).

### Measures of treatment effect

We analysed the treatment effects in the individual trials and reported risk ratio (RR) and risk difference (RD) for dichotomous data and mean difference (MD) for continuous data, with respective 95% confidence intervals (CI). We planned to determine the number needed to treat for an additional beneficial outcome (NNTB) or an additional harmful outcome (NNTH) for analyses with a statistically significant difference in the RD.

### Unit of analysis issues

The unit of analysis was the participating infant in individually randomised trials and the neonatal unit (or sub-unit) for cluster-randomised trials. For cluster-randomised trials, we planned to undertake analyses at the level of the individual while accounting for the clustering in the data using the methods recommended in the *Cochrane Handbook* (Higgins 2020).

### Dealing with missing data

We planned to request additional data from trial investigators when data on important outcomes were missing or reported unclearly. If unavailable, we planned to undertake sensitivity analyses to assess the potential impact on outcomes by excluding those trials with > 20% missing data.

### Assessment of heterogeneity

We examined the treatment effects of individual trials and heterogeneity between trial results by inspecting the forest plots. We calculated the  $I^2$  statistic for each analysis to quantify inconsistency across studies and describe the percentage of variability in effect estimates that may be due to heterogeneity rather than to sampling error. If we detected high levels of

heterogeneity ( $I^2 > 75\%$ ), we planned to explore the possible sources in subgroup analyses.

### Assessment of reporting biases

If at least 10 trials were included in a meta-analysis, we planned to examine a funnel plot for asymmetry visually and with Harbord's modification of Egger's test (Harbord 2006).

### Data synthesis

We used a fixed-effect model inverse variance meta-analysis for combining data where trials examined the same intervention and the populations and methods of the trials were judged to be similar.

### Subgroup analysis and investigation of heterogeneity

Where data were available, we planned subgroup analyses for the primary outcomes by:

- genus of probiotics or combinations (*Bifidobacterium spp.*, *Lactobacillus spp.*, *Saccharomyces spp.*, *Streptococcal spp.*, others, and combinations thereof);
- type of prebiotic oligosaccharide: natural versus synthetic;
- type of enteral feeding permitted for participating infants: human milk versus formula versus mixed;
- trials in which most (> 50%) participants were extremely low birth weight (ELBW; < 1000 g) or extremely preterm (< 28 weeks' gestation at birth) versus trials in which most infants were  $\geq$  28 weeks' gestation at birth of birth weight  $\geq$  1000 g;
- trials which restricted participation to infants with intrauterine growth restriction or absent or reversed end-diastolic flow velocities in the fetal aorta or umbilical artery versus trials that did not do so.

### Sensitivity analysis

We planned to undertake sensitivity analyses to determine how estimates are affected by including only studies at low risk of bias: (i) selection bias (adequate randomization and allocation concealment), (ii) detection or performance bias (adequate masking of intervention and measurement), (iii) attrition bias (< 20% loss to follow-up for primary outcome assessment), and (iv) reporting bias (selective reporting).

### Summary of findings and assessment of the certainty of the evidence

Two review authors (PTH, SO or WM) used the GRADE approach to assess the certainty of the evidence for effects on NEC, all-cause mortality before hospital discharge, late-onset invasive infection, and neurodevelopmental impairment (Schünemann 2013; Walsh 2021). We initially considered evidence from RCTs to be of high certainty, but downgraded the evidence certainty by one level for serious limitations (or by two levels for very serious limitations), based upon the following domains: risk of bias (study limitations), inconsistency across studies, indirectness of the evidence, imprecision of estimates, and presence of publication bias. This approach results in an assessment of the certainty of a body of evidence for a given outcome as one of four grades (Appendix 3).

- High certainty: further research is very unlikely to change our confidence in the estimate of effect.

- Moderate certainty: further research is likely to have an important impact on our confidence in the estimate of effect and may change the estimate.
- Low certainty: further research is very likely to have an important impact on our confidence in the estimate of effect and is likely to change the estimate.
- Very low certainty: we are very uncertain about the estimate.

We used the [GRADEpro GDT](#) software to create a 'Summary of findings' table to report the certainty of the evidence.

## RESULTS

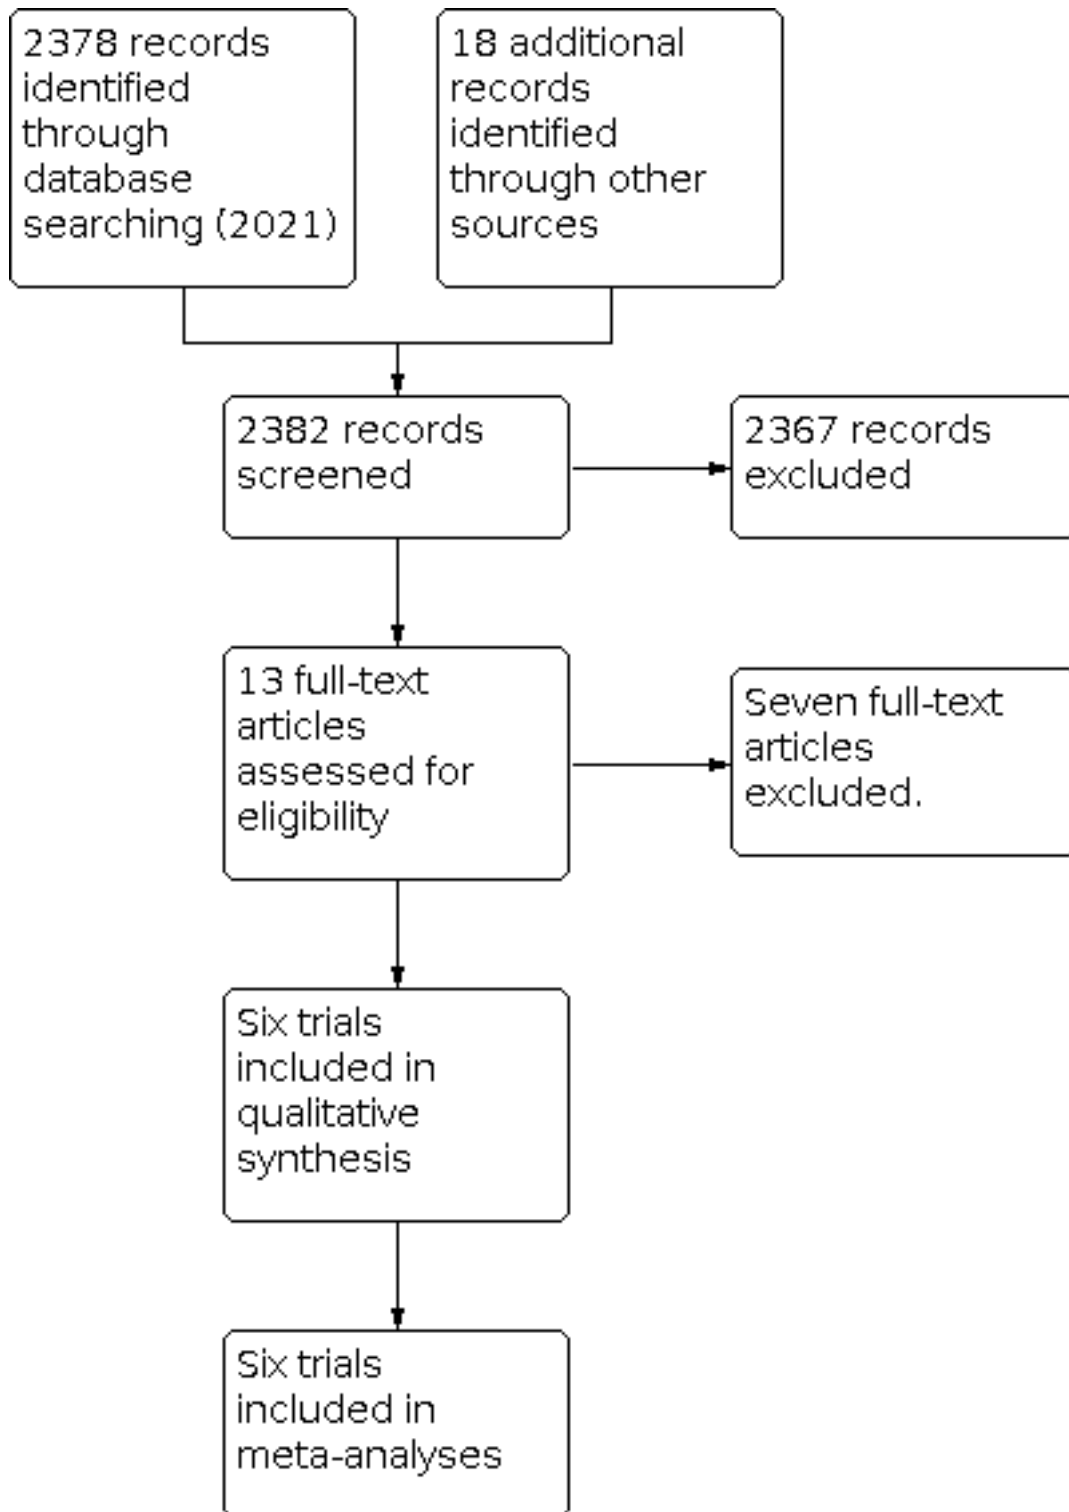

### Description of studies

See: [Characteristics of included studies](#); [Characteristics of excluded studies](#)

### Results of the search

After the removal of duplicates from the search results, we screened 2382 titles and abstracts, which included forward and backward citation searches, clinical trials registers and grey literature. We evaluated 13 articles sourced as full-text reports ([Figure 1](#)).

**Figure 1. Study flow diagram (June 2021)**

**Included studies**

We included six trials (See: [Characteristics of included studies](#)). These were conducted during the past 20 years in neonatal centres in Turkey ([Dilli 2015](#); [El 2017](#); [Guney-Varal 2017](#)), India ([Nandhini 2016](#); [Sreenivasa 2015](#)), and the USA ([Underwood 2009](#)). Most trials were conducted in single centres. One was a multi-centre trial ([Dilli](#)

[2015](#)). Individual infants were allocated randomly to intervention or control groups in all of the trials. No trial used a cluster design.

**Population**

In total, 925 infants participated in the trials. The median number of participants was 200 (range 90 to 220). Two trials enrolled only

very preterm or VLBW infants (Guney-Varal 2017; Nandhini 2016). The other trials enrolled infants of gestational age up to 34 or 35 weeks' (El 2017; Nandhini 2016; Sreenivasa 2015; Underwood 2009). Because the average gestation at birth was < 32 weeks', or the average birth weight < 1500 g, we included these trials. In one trial, participants were preterm infants with evidence of feed intolerance (El 2017). None of the trials excluded infants born 'small for gestational age' or with evidence of absent or reversed end-diastolic flow velocities in antenatal Doppler studies of the umbilical artery or fetal aorta.

Infants received an exclusive human milk diet in two of the trials (Nandhini 2016; Sreenivasa 2015). In the other trials, participating infants could be fed with human milk or formula or both (Dilli 2015; El 2017; Guney-Varal 2017; Underwood 2009), but reporting of outcome data was not stratified by these subgroups.

### Interventions

The studied synbiotics preparations contained lactobacilli or bifidobacteria (or both) combined with fructo-oligosaccharides (FOS) and galacto-oligosaccharides (GOS) or inulin (naturally occurring plant oligosaccharides).

- *Bifidobacterium spp.* plus inulin (Dilli 2015; El 2017)
- *Bifidobacterium spp.* and *Lactobacillus spp.* plus FOS/GOS (Guney-Varal 2017; Nandhini 2016)
- *Bifidobacterium spp.* and *Lactobacillus spp.* and *Streptococcus thermophiles* plus FOS (Sreenivasa 2015)
- *Bifidobacterium spp.* and *Lactobacillus spp.* or *Lactobacillus spp.* plus inulin (Underwood 2009)

### Comparisons

Two trials used placebo:

- Maltodextrin (Dilli 2015)
- Dilute elemental formula (Underwood 2009)

The other trials were unmasked and did not use a placebo (El 2017; Guney-Varal 2017; Nandhini 2016; Sreenivasa 2015).

### Outcomes

All trials reported the number of infants who developed NEC and all reported all-cause mortality prior to hospital discharge. Five trials reported the number of infants with at least one episode of culture-confirmed infection. In one trial, stool colonisation with the supplemented probiotic species was the primary outcome (Underwood 2009). Other in-hospital outcomes reported included time to establish full enteral feeding and duration of hospital stay. None of the trials reported long-term growth or neurodevelopmental outcomes.

### Excluded studies

We excluded seven reports of studies (Bering 2018; Dasopoulou 2015; Dilli 2013; Panigrahi 2008; Serce Pehlevan 2020; Underwood 2014; Vakiliamini 2020). The reasons for exclusion were ineligible population (three trials), wrong intervention (one trial), co-intervention (one trial), and non-randomised design (one trial). See [Characteristics of excluded studies](#).

### Risk of bias in included studies

'Risk of bias' assessments and judgements are described in [Characteristics of included studies](#) and are summarised in [Figure 2](#).

**Figure 2. Risk of bias summary: review authors' judgements about each risk of bias item for each included study.**

	Random sequence generation (selection bias)	Allocation concealment (selection bias)	Blinding of participants and personnel (performance bias): All outcomes	Blinding of outcome assessment (detection bias): All outcomes	Incomplete outcome data (attrition bias): All outcomes	Selective reporting (reporting bias)	Other bias
Dilli 2015	+	+	+	+	+	+	+
El 2017	?	+	-	-	+	+	-
Guney-Varal 2017	-	-	-	-	+	+	-
Nandhini 2016	+	+	-	-	+	+	+
Sreenivasa 2015	?	?	-	-	+	+	+
Underwood 2009	+	+	+	+	+	+	+

**Allocation**

Three trial reports described methods to generate random sequences (typically computer-generated) and to ensure adequate allocation concealment (typically sealed opaque envelopes) (Dilli 2015; Nandhini 2016; Underwood 2009). Two other reports did not describe these methods (El 2017; Sreenivasa 2015). One trial was quasi-randomised, employing alternate allocation (Guney-Varal 2017).

**Blinding**

Two of the trials were placebo-controlled (Dilli 2015; Underwood 2009). The other trials did not mask parents, caregivers, or clinical investigators (El 2017; Guney-Varal 2017; Nandhini 2016; Sreenivasa 2015).

**Incomplete outcome data**

All trials reported complete or near-complete assessments of primary outcomes.

**Selective reporting**

Although trial protocols were not available for most trials, selective reporting bias was not considered a major threat given that all relevant clinical outcomes were reported.

**Other potential sources of bias**

We did not find evidence of between-group baseline differences in participant characteristics or demographics in four of the trials (Dilli 2015; Nandhini 2016; Sreenivasa 2015; Underwood 2009). In two trials, including the quasi-randomised trial, the average birth weight (but not average gestational age) differed substantially between the groups (El 2017; Guney-Varal 2017).

**Effects of interventions**

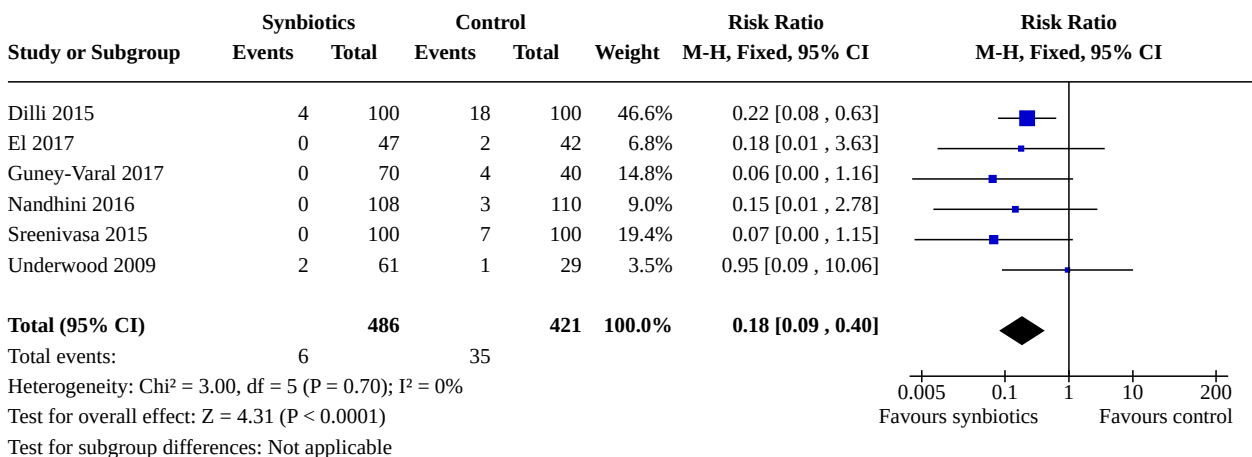

See: **Summary of findings 1** Synbiotics compared to control in very preterm or very low birth weight infants

**Primary outcomes**

**Necrotising enterocolitis**

Meta-analysis of data from six trials (907 infants) suggests that synbiotics (compared to no synbiotics) may reduce the risk of NEC prior to hospital discharge (Analysis 1.1; Figure 3):

**Figure 3. Forest plot of comparison: 1 Synbiotics versus control, outcome: 1.1 Necrotising enterocolitis.**

- RR 0.18, 95% CI 0.09 to 0.40
- RD 70 fewer per 1000, 95% CI 100 fewer to 40 fewer per 1000
- NNTB 14; 95% CI 10 to 25

**Subgroup analysis for heterogeneity**

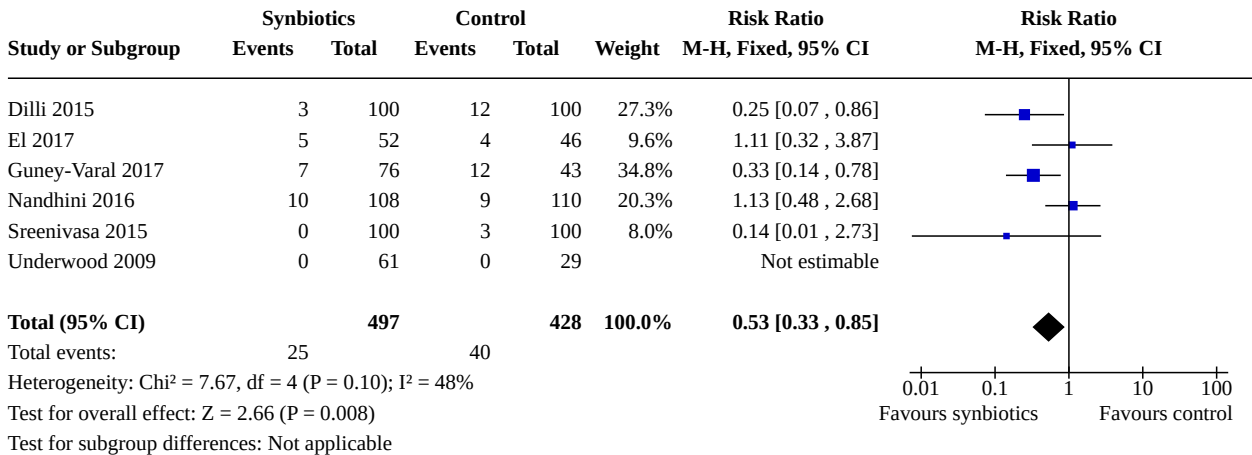

In the absence of high levels of heterogeneity (I<sup>2</sup> = 0%), we did not undertake the pre-specified subgroup analyses (Subgroup analysis and investigation of heterogeneity).

Using the GRADE approach, we assessed the certainty of the evidence to be 'low'. We downgraded evidence certainty by two levels for very serious study limitations (Summary of findings 1).

**All-cause mortality before hospital discharge**

Meta-analysis of data from six trials (925 infants) suggests that synbiotics (compared to no synbiotics) may reduce mortality prior to hospital discharge (Analysis 1.2; Figure 4).

Figure 4. Forest plot of comparison: 1 Synbiotics versus control, outcome: 1.2 All-cause mortality.

- RR 0.53, 95% CI 0.33 to 0.85
- RD 50 per 1000 fewer, 95% CI 120 fewer to 100 fewer per 1000
- NNTB 20, 95% CI 8 to 100

Subgroup analysis for heterogeneity

In the absence of high levels of heterogeneity (I<sup>2</sup> = 48%), we did not undertake the pre-specified subgroup analyses (Subgroup analysis and investigation of heterogeneity).

We assessed the certainty of evidence to be 'low'. We downgraded evidence certainty by one level (because of objectivity of the

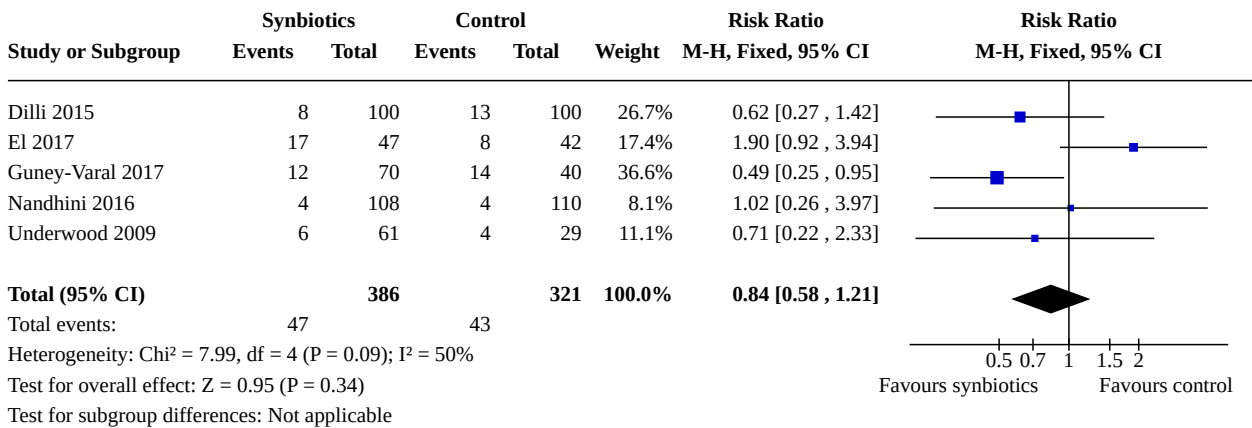

outcome) for serious study limitations and by one level for imprecision (Summary of findings 1).

Secondary outcomes

Late-onset invasive infection

Meta-analysis of data from five trials (707 infants) suggests that synbiotics (compared to no synbiotics) may result in little or no difference in risk of late-onset invasive infection, but the evidence is very uncertain (Analysis 1.3; Figure 5).

Figure 5. Forest plot of comparison: 1 Synbiotics versus control, outcome: 1.3 Infection.

- RR 0.84, 95% CI 0.58 to 1.21
- RD 20 per 1000 fewer, 95% CI 70 fewer to 30 more per 1000

Subgroup analysis for heterogeneity

In the absence of high levels of heterogeneity (I<sup>2</sup> = 50%), we did not undertake the pre-specified subgroup analyses (Subgroup analysis and investigation of heterogeneity).

We assessed the certainty of evidence to be 'very low'. We downgraded by two levels for very serious study limitations and by one level for serious imprecision (Summary of findings 1).

Invasive infection with the supplemented probiotic micro-organism

None of the trials reported any episodes of infection with the supplemented probiotic micro-organisms.

Duration of hospitalisation

Two trials showed a reduced duration of hospitalizations with synbiotics compared to no synbiotics (median difference eight to nine days).

- [Dilli 2015](#): median 42 versus 50 days
- [Guney-Varal 2017](#): Median 41 versus 50 days

Three trials did not show a difference.

- [El 2017](#): median 34 versus 31 days
- [Nandhini 2016](#): mean 8.3 versus 8.4 days
- [Sreenivasa 2015](#): mean 13.7 versus 13.6 days

One trial did not report duration of hospitalisation ([Underwood 2009](#)).

### Neurodevelopmental outcomes

No trial assessed neurodevelopmental outcomes.

### Sensitivity analyses of trials at low risk of bias

We undertook sensitivity meta-analyses of data from the two trials (290 infants) that were assessed as having low overall risk of bias ([Dilli 2015](#); [Underwood 2009](#)). These showed similar results compared with the primary analyses.

- NEC: RR 0.27, 95% CI 0.11 to 0.69; RD 100 fewer per 1000, 95% CI 170 fewer to 40 fewer; NNTB 10, 95% CI 6 to 25 ([Analysis 2.1](#))
- All-cause mortality prior to hospital discharge: RR 0.25, 95% CI 0.07 to 0.86; RD 60 fewer per 1000, 95% CI 120 fewer to 10 fewer; NNTB 17, 95% CI 8 to 100 ([Analysis 2.2](#))
- Late-onset invasive infection: RR 0.64, 95% CI 0.33 to 1.28; RD 50 fewer per 1000, 95% CI 120 fewer to 30 more ([Analysis 2.3](#))

Neither trial assessed neurodevelopmental outcomes.

## DISCUSSION

### Summary of main results

Meta-analyses of data from six trials, with 925 participants in total, show that enteral supplementation with synbiotics may reduce the risk of NEC and all-cause mortality prior to hospital discharge in very preterm or VLBW infants (low certainty evidence). Meta-analysis of data from five trials, with 707 participants, shows that synbiotics may have little or no impact on the risk of late-onset invasive infection, but the evidence is of very low certainty. No trial assessed neurodevelopmental outcomes.

### Overall completeness and applicability of evidence

These data are likely to be relevant to current practice since all of the included trials were conducted during the past 20 years in neonatal care facilities in a variety of settings (India, Turkey, USA). The risk of developing NEC amongst the control infants was about 8% (compared with 1% in the intervention group), similar to incidence estimates from recent observational studies ([Battersby 2018](#); [Horbar 2012](#)). While most participants were very preterm or VLBW infants, few were extremely preterm or ELBW. One trial recruited infants with feeding intolerance ([El 2017](#)). Although it is unclear whether feeding intolerance is independently predictive of NEC, findings in this selected population may not be generalisable to all very preterm or VLBA infants. None of the trials specifically excluded infants born 'small for gestational age' or with evidence of absent or reversed end-diastolic flow velocities in antenatal Doppler studies of the umbilical artery or fetal aorta. Consequently, the applicability of the review findings to the population of

preterm infants at highest risk of NEC and associated mortality and morbidity is uncertain.

The type of milk feeds that infants receive might influence the effects of synbiotics supplementation. Evidence exists that human milk rather than formula feeding reduces the risk of NEC ([Quigley 2019](#)). Two trials permitted only human milk feeding, while in the other four trials infants could be fed with human milk or formula or both. In the absence of high levels of heterogeneity, we did not undertake any subgroup analyses by type of milk feeding. Any such analysis, furthermore, would need to be interpreted cautiously as the data available were insufficient to define subgroups at an infant (rather than trial) level. The possibility remains that infants who receive human milk as their predominant source of nutrition might not gain added benefit from synbiotics supplementation since their milk is already rich in prebiotic human milk oligosaccharides that enhance probiotic growth and colonisation. Conversely, it is feasible that exclusively formula-fed infants may experience less benefit than human milk-fed infants because their diet lacks natural prebiotics that can enhance the growth and colonisation of the exogenous probiotics in the synbiotics supplement. A better understanding of the mechanisms and events occurring at the intestinal epithelial and mucosal level may help to determine which combinations of probiotics and prebiotics optimally supports a putatively beneficial microbiome in very preterm or VLBW infants receiving different types of milk feeds ([Nolan 2020](#)).

### Quality of the evidence

We used GRADE methods to assess the certainty of the evidence for effects on NEC, all-cause mortality prior to hospital discharge, late-onset invasive infection, and neurodevelopmental impairment ([Summary of findings 1](#)). The certainty of the evidence was downgraded because of methodological weaknesses (risk of bias) in four of the six trials. These included lack of masking measures for parents, caregivers, and clinical assessors that may have introduced performance and detection biases and caused an overestimation of effect estimates, particularly for NEC, given the subjectivity of this diagnosis. Pre-specified sensitivity analyses of the two trials at overall low risk of bias showed effects consistent with those in the primary meta-analyses that included all the trials. These analyses, however, included data from only 290 infants (with fewer than 25 episodes of NEC and 15 deaths) and consequently generated imprecise estimates of effect.

The other reason for downgrading the certainty of the evidence was the existence of substantial imprecision in estimates of effect, with meta-analyses generating 95% CI that included large benefit as well as small or no benefit or harm. Although the total number of participants in the included trials was more than 900, not all trials contributed data to all outcome estimates. Estimates of effect were consequently imprecise, especially for less common outcomes, including all-cause mortality prior to hospital discharge, where the 95% CI ranged from an NNTB of 8 to 100 infants. Such imprecise estimates of effect are unlikely to meaningfully inform decision-making in this context.

### Potential biases in the review process

An important concern with the review process is the possibility that the findings are subject to publication and other reporting biases ([Hopewell 2009](#)). Data from trials which show statistically significant or potentially important effects tend to be more readily

available for inclusion in meta-analyses (Gale 2020). Publication bias, as well as other sources of small-study bias, is an important contributor to inflation of effect size estimates in meta-analyses of interventions to improve outcomes in very preterm or VLBW infants (Young 2021). For example, the Cochrane Review of probiotics to prevent NEC in very preterm or VLBW infants shows a large reduction in the risk of NEC, but the funnel plot and regression analysis indicate that publication bias is likely to have inflated the pooled effect size estimate (Sharif 2020).

In this review, we could not assess whether publication bias (or related small study biases) exaggerated the effect size since the meta-analyses contained insufficient data points (fewer than 10) to make funnel plot inspection and regression analysis valid and reliable; that is, able to distinguish real asymmetry from chance asymmetry (Higgins 2020). Although we attempted to minimise the threat of publication bias by screening the reference lists of included trials and related reviews and searching the proceedings of the major international perinatal conferences to identify trial reports that are not published in full form in academic journals, we cannot be sure that other trials have been undertaken but not reported.

### Agreements and disagreements with other studies or reviews

We are not aware of any other systematic reviews that have assessed the trial evidence for synbiotics supplementation in very preterm or VLBW infants. Other Cochrane Reviews address whether probiotics alone or prebiotics alone affect the risk of NEC (Sharif 2020; Sharif 2021a). Meta-analyses of data from trials of probiotic supplementation suggest a reduction in the risk of NEC and associated morbidity and all-cause mortality for very preterm or very low birth weight infants. Similar to the findings in this review, however, concerns about trial quality, heterogeneity of interventions, and publication bias, as well as the paucity of data for extremely preterm or ELBW infants, means that these findings are of low certainty, and should be interpreted and applied cautiously.

A large cluster-randomised controlled trial of a synbiotics supplementation for newborn infants was not eligible for inclusion in this review because participants were not very preterm or VLBW (Panigrahi 2017). This community-based trial, undertaken in rural India between 2008 to 2016, enrolled newborn infants who were at least 2000 g and at least 35 weeks' gestation at birth (N = 4556). Infant participants were randomly allocated (by village clusters) to receive a synbiotics preparation of *Lactobacillus plantarum* plus fructo-oligosaccharides or placebo. Analysis showed a 40% reduction in the primary outcome, which was a composite of "sepsis or death." Necrotising enterocolitis was not an outcome of interest, given its rarity in this population. The trial was of high methodological quality, although substantially more infants in the synbiotics group were lost to follow-up (outcomes not assessed) than in the placebo group. Given the differences in population, setting, and types of morbidity, the applicability of this trial's findings to very preterm or VLBW infants is limited.

## AUTHORS' CONCLUSIONS

### Implications for practice

The available trial data provide only low-certainty evidence about the effects of synbiotics on the risk of necrotising enterocolitis (NEC) and associated morbidity and all-cause mortality for very preterm or very low birth weight infants. Considerable uncertainty exists about how to interpret and apply these trial data because our confidence in the effect estimates is limited; the true effects may be substantially different from these estimates. In addition to concern that effect size estimates are inflated by biases in the existing trials, a major barrier to implementing the findings is that existing analyses are not able to determine reliably the optimal constitution of synbiotics (strains, doses, timing of introduction, duration of use) for routine prophylactic use. A variety of commercially available synbiotics preparations are in use in a minority of neonatal units internationally, but widespread use is limited by availability and regulatory and licensing issues. Furthermore, important safety concerns persist, given that probiotic bacteraemia or fungaemia have been reported in preterm infants receiving probiotic supplements (Bertelli 2015; Esaïassen 2016; Jenke 2012; Zbinden 2015).

### Implications for research

Given the low level of certainty about whether (and which) synbiotics affect important outcomes in very preterm or very low birth weight (VLBW) infants, further assessment in high-quality randomised, placebo-controlled trials is needed to inform policy and practice. Such trials are likely to need to recruit at least 2000 participants to reliably detect plausible effects on uncommon outcomes such as NEC and mortality prior to hospital discharge (Gale 2020). Ideally, any planned trials should attempt to ensure that caregivers and assessors are masked to the intervention, as investigation and diagnosis of NEC, late-onset invasive infection and neurodevelopmental impairment can be subjective, and can be associated with the inter-rater variation. While it may be appropriate to be broadly inclusive of very preterm and VLBW infant participants, trials should ensure sufficient power to assess effects in extremely preterm or extremely low birth weight (ELBW) infants, infants born 'small for gestational age', or with evidence of absent or reversed end-diastolic flow velocities in antenatal Doppler studies of the umbilical artery or fetal aorta. Trials should also explore interactions with the type of enteral feed received (Griffiths 2018).

A key concern in planning any trial is choosing the appropriate intervention to assess (Poindexter 2021). Investigators could consider whether trials using synbiotics are merited alongside trials of probiotics and prebiotics alone, including as part of a factorial or an adaptive design (Underwood 2019). Unit of randomization and analysis is another consideration. Although individual infant randomisation is preferred for statistical and analytical reasons, concern exists that cross-contamination of the probiotic microorganisms to infants in the control group would limit the power of the trial to detect an effect. Randomising at the neonatal care centre level (cluster-randomised controlled trial) obviates this problem, although it inflates the sample size requirement considerably due to the inter-cluster correlation of outcomes (Gale 2020).

## ACKNOWLEDGEMENTS

Cochrane Neonatal supported the authors in the development of this review. We thank Colleen Ovelman and Jane Cracknell (former Managing Editors), Michelle Fiander, (Information Specialist and current Managing Editor), and Roger Soll (Coordinating editor).

We thank Melissa Harden (Information Specialist, Centre for Reviews and Dissemination, University of York, UK) for the electronic search strategy and database management.

William McGuire is a member of the Cochrane Neonatal group but was not involved in the editorial process or decision-making for this review.

Editorial and peer-review contribution:

- Sign-off Editor (final editorial decision): Robert Boyle, Imperial College London
- Managing editor (selected peer reviewers, provided comments, collated peer-reviewer comments, provided editorial guidance to authors, edited the article): Lara Kahale, Cochrane Central Editorial Service
- Editorial Assistant (conducted editorial policy checks and supported editorial team): Leticia Rodrigues, Cochrane Central Editorial Service
- Copy Editor (copy-editing and production): Hacsı Horváth, Cochrane Copy Edit Support
- Peer reviewers (provided comments and recommended an editorial decision): William W. Hay, Jr., University of Colorado, Denver, Colorado, USA; Rosemary D. Higgins, George Mason University, Fairfax, Virginia, USA (clinical review); Mara Marongiu, IRGB-CNR, Sardinia- Italy (consumer review); Sarah Hodgkinson, Evidence Production and Methods Directorate, Cochrane (methods review); Samantha Cox, Information Specialist Cochrane ENT (search review)

**CHARACTERISTICS OF STUDIES**
**Characteristics of included studies** [ordered by study ID]

**Dilli 2015**
**Study characteristics**

Methods	RCT
Participants	200 very preterm or VLBW infants
Interventions	Synbiotics (N = 100): <i>Bifidobacterium lactis</i> (5 x 10 <sup>9</sup> colony-forming units (cfu)) plus inulin (900 mg) added to human milk or formula once daily for 8 weeks (or until hospital discharge)  Control (N = 100): maltodextrin powder placebo
Outcomes	<ul style="list-style-type: none"> <li>• NEC</li> <li>• Death</li> <li>• Invasive infection</li> <li>• Length of hospital stay</li> </ul>
Notes	Setting: Turkey (5 centres: 2011 to 14)  Funding: not stated  NB. This was a 4-arm RCT- 2 other groups were <i>probiotic</i> only (N = 100) and <i>prebiotic</i> only (N = 100)

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Computer-generated sequence
Allocation concealment (selection bias)	Low risk	Sealed opaque envelopes

**Dilli 2015** (Continued)

Blinding of participants and personnel (performance bias) All outcomes	Low risk	Masked (placebo-controlled)
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Masked (placebo-controlled)
Incomplete outcome data (attrition bias) All outcomes	Low risk	Complete reporting
Selective reporting (reporting bias)	Low risk	Unlikely
Other bias	Low risk	No evidence baseline imbalance

**El 2017**
**Study characteristics**

Methods	RCT
Participants	98 preterm (< 35 weeks) or low birth weight (< 2500 g) infants with feed intolerance
Interventions	Synbiotics (N = 52): <i>Bifidobacterium lactis</i> ( $5 \times 10^9$ cfu) plus inulin (900 mg) diluted in distilled water and given 3 times a day with human milk or formula for 10 days.  Control (N = 46): no synbiotic supplement
Outcomes	<ul style="list-style-type: none"> <li>• NEC</li> <li>• Death</li> <li>• Invasive infection</li> <li>• Length of hospital stay</li> </ul>
Notes	Turkey (single centre: 2010 to 13)  Funding: not stated

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	No information on randomization method
Allocation concealment (selection bias)	Low risk	Quote: "by balanced blocks using sealed envelopes"
Blinding of participants and personnel (performance bias) All outcomes	High risk	Unmasked

**El 2017** (Continued)

Blinding of outcome assessment (detection bias) All outcomes	High risk	Unmasked
Incomplete outcome data (attrition bias) All outcomes	Low risk	Complete reporting for primary outcomes
Selective reporting (reporting bias)	Low risk	No access to protocol but unlikely
Other bias	High risk	Differences in baseline birth weight (1270 versus 1410 g), no difference in gestational age at birth (31 versus 31 weeks)

**Guney-Varal 2017**
**Study characteristics**

Methods	RCT
Participants	110 preterm (< 33 weeks) or VLBW infants
Interventions	Synbiotics (N = 76): <i>Lactobacillus rhamnosus</i> ( $4 \times 10^8$ cfu) + <i>L. casei</i> ( $8 \times 10^8$ cfu) + <i>L. plantarum</i> ( $4 \times 10^8$ cfu) + <i>Bifidobacterium animalis</i> ( $4 \times 10^8$ cfu) plus FOS (383 mg) and GOS (100 mg) added to human milk or formula daily until hospital discharge  Control (N = 43): no synbiotic supplement
Outcomes	<ul style="list-style-type: none"> <li>• NEC</li> <li>• Death</li> <li>• Invasive infection</li> <li>• Length of hospital stay</li> </ul>
Notes	Turkey (single centre: 2013 to 2016)  Funding: not stated

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	High risk	Quote. "Alternate randomization" (quasi-randomised)
Allocation concealment (selection bias)	High risk	Quote: "Alternate randomization"
Blinding of participants and personnel (performance bias) All outcomes	High risk	Unmasked
Blinding of outcome assessment (detection bias) All outcomes	High risk	Unmasked

**Guney-Varal 2017** (Continued)

Incomplete outcome data (attrition bias) All outcomes	Low risk	Complete reporting for primary outcomes
Selective reporting (reporting bias)	Low risk	No access to protocol but unlikely
Other bias	High risk	Differences in baseline birth weight (1728 versus 1228 g), but no difference in gestational age at birth (29.7 versus 29.3 weeks)

**Nandhini 2016**
**Study characteristics**

Methods	RCT
Participants	220 preterms (28 to 34 weeks) infants (most participants very preterm or VLBW)
Interventions	Synbiotics (N = 110): <i>Lactobacillus casei</i> ( $3 \times 10^8$ cfu) + <i>L. rhamnosus</i> ( $4 \times 10^8$ cfu) + <i>L. plantaris</i> ( $3 \times 10^8$ cfu) + <i>L. bulgaricus</i> ( $3 \times 10^8$ cfu) + <i>Bifidobacterium infantis</i> ( $3 \times 10^8$ cfu) + <i>B. breve</i> ( $3 \times 10^8$ cfu) + <i>B. longum</i> ( $4 \times 10^8$ cfu) plus FOS (100 mg) added to maternal milk twice daily for 7 days  Control (N= 43): no synbiotic supplement
Outcomes	<ul style="list-style-type: none"> <li>• NEC</li> <li>• Death</li> <li>• Invasive infection</li> <li>• Length of hospital stay</li> </ul>
Notes	India (single centre: study dates not stated)  Funding: not stated

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Computer-generated random numbers
Allocation concealment (selection bias)	Low risk	Opaque sealed envelopes
Blinding of participants and personnel (performance bias) All outcomes	High risk	Unmasked
Blinding of outcome assessment (detection bias) All outcomes	High risk	Unmasked
Incomplete outcome data (attrition bias) All outcomes	Low risk	Complete reporting for primary outcomes

**Nandhini 2016** (Continued)

Selective reporting (reporting bias)	Low risk	All outcomes listed in protocol reported
Other bias	Low risk	No evidence baseline imbalance

**Sreenivasa 2015**
**Study characteristics**

Methods	RCT
Participants	200 preterm (< 34 weeks) infants (most participants very preterm or VLBW)
Interventions	<p>Synbiotics (N = 100): <i>Lactobacillus acidophilus</i> (<math>3 \times 10^8</math> cfu) + <i>Bifidobacterium longum</i> (<math>1.5 \times 10^8</math> cfu) + <i>B. bifidum</i> (<math>1.5 \times 10^8</math> cfu) + <i>Streptococcus thermophiles</i> (<math>1.5 \times 10^8</math> cfu) plus FOS (100 mg) added to maternal milk twice daily from onset of enteral feeding until infant accepted full enteral feeds</p> <p>Control (N= 100): no synbiotic supplement</p>
Outcomes	<ul style="list-style-type: none"> <li>• NEC</li> <li>• Death</li> <li>• “Sepsis”- culture-confirmed invasive infection not reported</li> <li>• Length of hospital stay</li> </ul>
Notes	<p>India (single centre: 2012 to 2014)</p> <p>Funding: (quote:) “No funding sources”</p> <p>Investigators contacted for unpublished data (June 2021)</p>

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	No details on random generation (quote: “simple random sampling”)
Allocation concealment (selection bias)	Unclear risk	No details on allocation concealment
Blinding of participants and personnel (performance bias) All outcomes	High risk	Unmasked
Blinding of outcome assessment (detection bias) All outcomes	High risk	Unmasked
Incomplete outcome data (attrition bias) All outcomes	Low risk	Complete reporting for primary outcomes
Selective reporting (reporting bias)	Low risk	No access to protocol but unlikely

**Sreenivasa 2015** (Continued)

Other bias	Low risk	No evidence baseline imbalance
------------	----------	--------------------------------

**Underwood 2009**
**Study characteristics**

Methods	RCT
Participants	90 preterm (< 35 weeks) or low birth weight (750 to 2000 g) infants (most participants very preterm or VLBW)
Interventions	<p>[3-arm trial]</p> <p>Synbiotics (N = 61): (i) <i>Lactobacillus rhamnosus</i> (<math>5 \times 10^8</math> cfu) OR (ii) <i>L. acidophilus</i> (<math>1 \times 10^{10}</math> cfu) + <i>Bifidobacterium longum</i> (<math>5 \times 10^8</math> cfu) + <i>B. bifidum</i> (cfu) + <i>B. infantis</i> (<math>5 \times 10^8</math> cfu) plus inulin (dose not stated) given twice daily dissolved in saline for 28 days or until hospital discharge</p> <p>Control (N = 29): placebo (1:30 dilute preparation of elemental formula)</p> <p>Participating infants were fed with human milk or formula (or both).</p>
Outcomes	<ul style="list-style-type: none"> <li>• Stool colonisation with probiotic species (primary outcome)</li> <li>• NEC</li> <li>• Death</li> <li>• Invasive infection</li> </ul>
Notes	<p>USA (single centre: 2004- 06)</p> <p>Funding: NIH UC Davis K30 Program (#UL1RR024146, MAU) and the Children's Miracle network (CLB).</p>

**Risk of bias**

Bias	Authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Computer-generated
Allocation concealment (selection bias)	Low risk	Pharmacy-assigned
Blinding of participants and personnel (performance bias) All outcomes	Low risk	Masked (placebo-controlled)
Blinding of outcome assessment (detection bias) All outcomes	Low risk	Masked (placebo-controlled)
Incomplete outcome data (attrition bias) All outcomes	Low risk	Complete reporting
Selective reporting (reporting bias)	Low risk	Unlikely

**Underwood 2009** (Continued)

Other bias                      Low risk                      No evidence baseline imbalance

**cfu**: colony-forming units; **FOS**: fructo-oligosaccharides; **GOS**: galacto-oligosaccharides; **NEC**: necrotising enterocolitis; **NIH**: National Institutes of Health; **RCT**: randomized controlled trial; **VLBW**: very low birth weight

**Characteristics of excluded studies** [ordered by study ID]

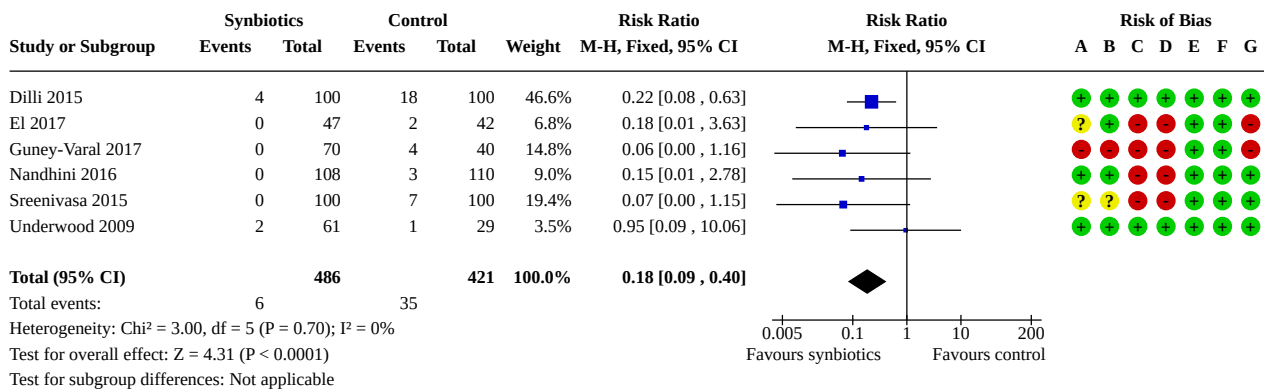

Study	Reason for exclusion
Bering 2018	Not an RCT
Dasopoulou 2015	RCT of prebiotics
Dilli 2013	Participants were not very preterm or VLBW
Panigrahi 2008	Participants were not very preterm or VLBW
Serce Pehlevan 2020	RCT - the intervention group also received lactoferrin (co-intervention)
Underwood 2014	RCT comparing supplementation of formula with either prebiotic oligosaccharides or (quote:) "a pooled concentrated donor human milk product"
Vakiliamini 2020	Most participants were not very preterm or VLBW (subgroup data not available)

**RCT**: randomized controlled trial; **VLBW**: very low birth weight

**DATA AND ANALYSES**
**Comparison 1. Synbiotics versus control**

Outcome or subgroup title	No. of studies	No. of participants	Statistical method	Effect size
1.1 Necrotising enterocolitis	6	907	Risk Ratio (M-H, Fixed, 95% CI)	0.18 [0.09, 0.40]
1.2 All-cause mortality	6	925	Risk Ratio (M-H, Fixed, 95% CI)	0.53 [0.33, 0.85]
1.3 Invasive infection	5	707	Risk Ratio (M-H, Fixed, 95% CI)	0.84 [0.58, 1.21]

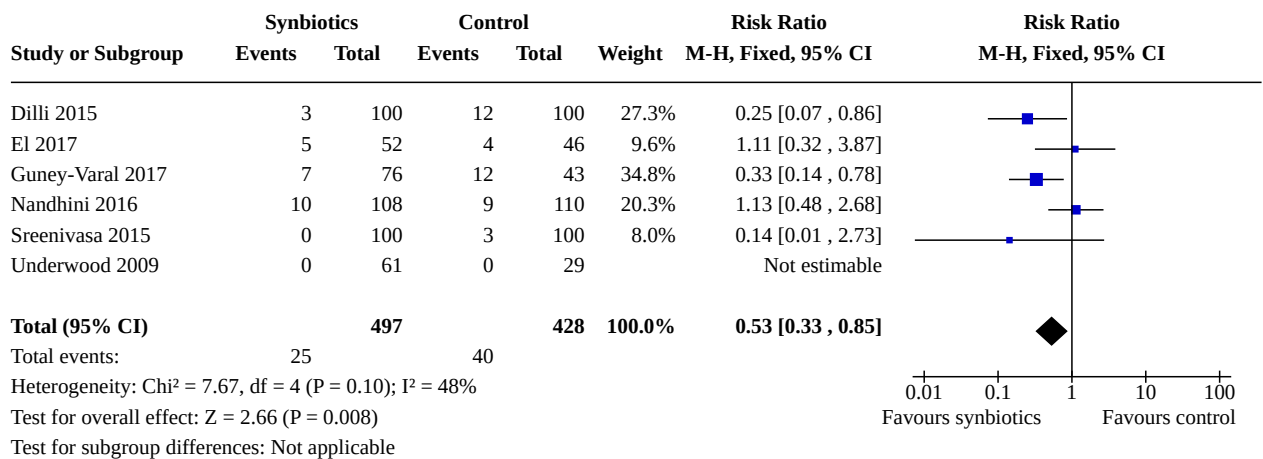

**Analysis 1.1. Comparison 1: Synbiotics versus control, Outcome 1: Necrotising enterocolitis**

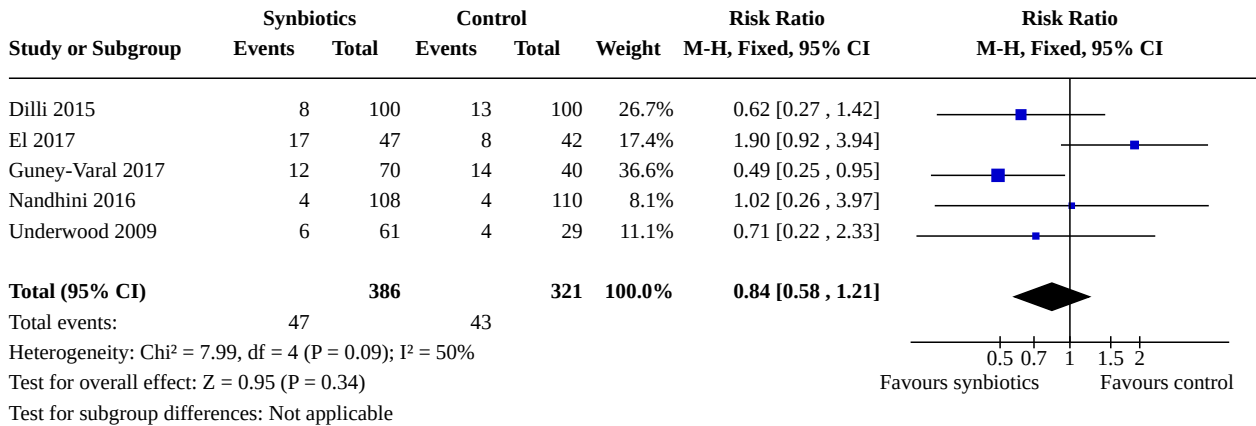

**Risk of bias legend**

- (A) Random sequence generation (selection bias)
- (B) Allocation concealment (selection bias)
- (C) Blinding of participants and personnel (performance bias)
- (D) Blinding of outcome assessment (detection bias)
- (E) Incomplete outcome data (attrition bias)
- (F) Selective reporting (reporting bias)
- (G) Other bias

**Analysis 1.2. Comparison 1: Synbiotics versus control, Outcome 2: All-cause mortality**

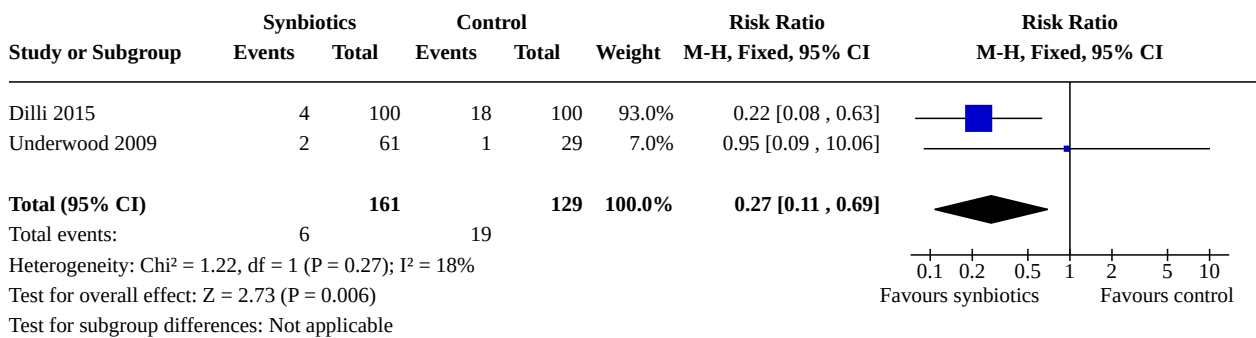

**Analysis 1.3. Comparison 1: Synbiotics versus control, Outcome 3: Invasive infection**

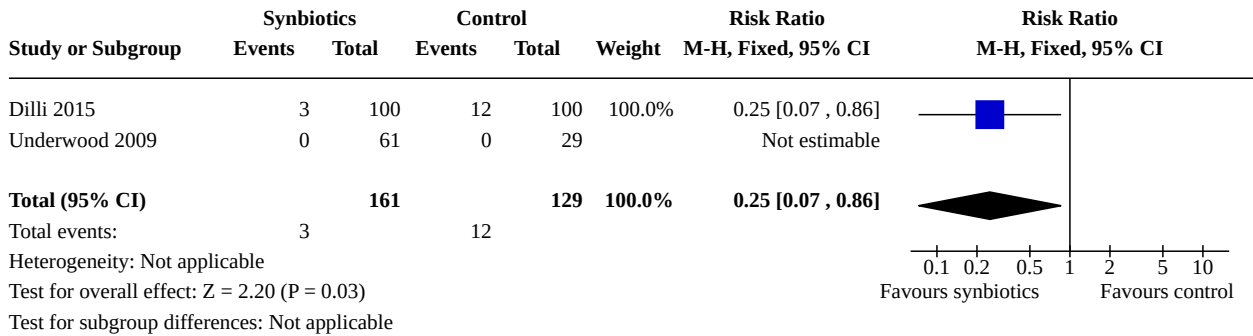

**Comparison 2. Synbiotics versus control (trials at low risk of bias)**

Outcome or subgroup title	No. of studies	No. of participants	Statistical method	Effect size
2.1 Necrotising enterocolitis	2	290	Risk Ratio (M-H, Fixed, 95% CI)	0.27 [0.11, 0.69]
2.2 All cause mortality	2	290	Risk Ratio (M-H, Fixed, 95% CI)	0.25 [0.07, 0.86]
2.3 Invasive infection	2	290	Risk Ratio (M-H, Fixed, 95% CI)	0.64 [0.33, 1.28]

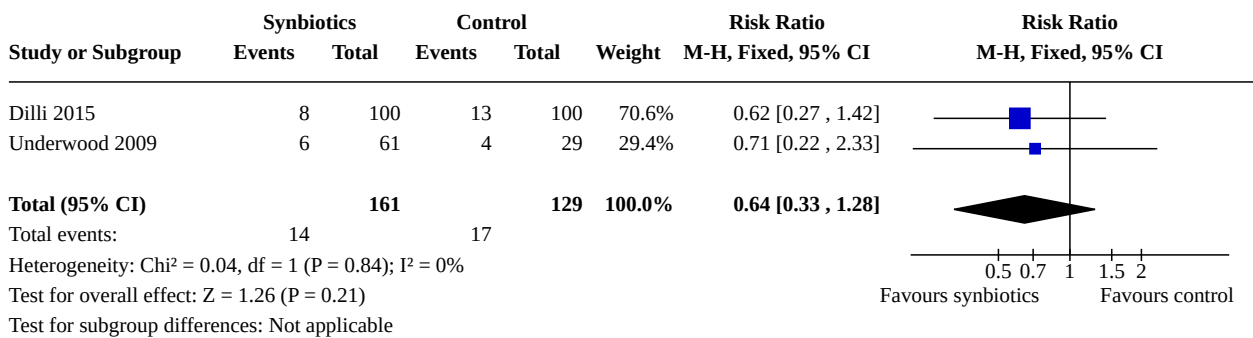

**Analysis 2.1. Comparison 2: Synbiotics versus control (trials at low risk of bias), Outcome 1: Necrotising enterocolitis**

**Analysis 2.2. Comparison 2: Synbiotics versus control (trials at low risk of bias), Outcome 2: All cause mortality**

**Analysis 2.3. Comparison 2: Synbiotics versus control (trials at low risk of bias), Outcome 3: Invasive infection**

## Appendix 2. 'Risk of bias' tool

### Sequence generation (checking for possible selection bias). Was the allocation sequence adequately generated?

For each included study, we categorised the method used to generate the allocation sequence as:

- low risk (any truly random process e.g. random number table; computer random number generator);
- high risk (any non-random process e.g. odd or even date of birth; hospital or clinic record number); or
- unclear risk.

### Allocation concealment (checking for possible selection bias). Was allocation adequately concealed?

For each included study, we categorised the method used to conceal the allocation sequence as:

- low risk (e.g. telephone or central randomisation; consecutively numbered sealed opaque envelopes);
- high risk (open random allocation; unsealed or non-opaque envelopes, alternation; date of birth); or
- unclear risk.

**Blinding of participants and personnel (checking for possible performance bias). Was knowledge of the allocated intervention adequately prevented during the study?**

For each included study, we categorised the methods used to blind study participants and personnel from knowledge of which intervention a participant received. Blinding was assessed separately for different outcomes or class of outcomes. We categorised the methods as:

- low risk, high risk or unclear risk for participants; and
- low risk, high risk or unclear risk for personnel.

**Blinding of outcome assessment (checking for possible detection bias). Was knowledge of the allocated intervention adequately prevented at the time of outcome assessment?**

For each included study, we categorised the methods used to blind outcome assessment. Blinding was assessed separately for different outcomes or class of outcomes. We categorised the methods as:

- low risk for outcome assessors;
- high risk for outcome assessors; or
- unclear risk for outcome assessors.

**Incomplete outcome data (checking for possible attrition bias through withdrawals, dropouts, protocol deviations). Were incomplete outcome data adequately addressed?**

For each included study and for each outcome, we described the completeness of data including attrition and exclusions from the analysis. We noted whether attrition and exclusions were reported, the numbers included in the analysis at each stage (compared with the total randomised participants), reasons for attrition or exclusion where reported, and whether missing data were balanced across groups or were related to outcomes. Where sufficient information was reported or supplied by the trial authors, we re-included missing data in the analyses. We categorised the methods as:

- low risk (< 20% missing data);
- high risk ( $\geq$  20% missing data); or
- unclear risk.

**Selective reporting bias. Are reports of the study free of suggestion of selective outcome reporting?**

For each included study, we described how we investigated the possibility of selective outcome reporting bias and what we found. For studies in which study protocols were published in advance, we compared prespecified outcomes versus outcomes eventually reported in the published results. If the study protocol was not published in advance, we contacted study authors to gain access to the study protocol. We assessed the methods as:

- low risk (where it is clear that all of the study's prespecified outcomes and all expected outcomes of interest to the review have been reported);
- high risk (where not all the study's prespecified outcomes have been reported; one or more reported primary outcomes were not prespecified outcomes of interest and are reported incompletely and so cannot be used; study fails to include results of a key outcome that would have been expected to have been reported); or
- unclear risk.

**Other sources of bias. Was the study apparently free of other problems that could put it at a high risk of bias?**

For each included study, we described any important concerns we had about other possible sources of bias (for example, whether there was a potential source of bias related to the specific study design or whether the trial was stopped early due to some data-dependent process). We assessed whether each study was free of other problems that could put it at risk of bias as:

- low risk;
- high risk; or
- unclear risk.

If needed, we explored the impact of the level of bias through undertaking sensitivity analyses.

**Appendix 3. GRADE**

GRADE considers that evidence from randomised controlled trials is of high certainty, but that assessment may be downgraded based on consideration of any of five areas.

- Design (risk of bias).
- Consistency across studies.

- Directness of evidence.
- Precision of estimates.
- Presence of publication bias.

Usually, the certainty rating will be downgraded by one level for each factor, up to a maximum of three levels for all factors. If there are very severe problems for any one factor (e.g. when assessing limitations in design and implementation, all trials were unconcealed, unmasked, and lost over 50% of their participants to follow-up), trial evidence may be downgraded by two levels due to that factor alone.

The GRADE approach results in an assessment of the certainty of a body of evidence as one of four grades.

- High certainty: further research is very unlikely to change our confidence in the estimate of effect.
- Moderate certainty: further research is likely to have an important impact on our confidence in the estimate of effect and may change the estimate.
- Low certainty: further research is very likely to have an important impact on our confidence in the estimate of effect and is likely to change the estimate.
- Very low certainty: we are very uncertain about the estimate.

## HISTORY

Protocol first published: Issue 5, 2021

## CONTRIBUTIONS OF AUTHORS

All authors contributed equally to the development and completion of the review.

## DECLARATIONS OF INTEREST

SS has declared that she has no conflict of interest.

PTH has declared that he has no conflict of interest.

SJO has declared that he has no conflict of interest.

WM is a co-ordinating editor of Cochrane Neonatal but was not involved in the editorial process or decision-making for this review.

## SOURCES OF SUPPORT

### Internal sources

- Centre for Reviews and Dissemination, University of York, UK

Logistical support.

### External sources

- Vermont Oxford Network, USA

Cochrane Neonatal Reviews are produced with support from Vermont Oxford Network, a worldwide collaboration of health professionals dedicated to providing evidence-based care of the highest quality for newborn infants and their families.

- National Institute for Health Research (NIHR), UK

This report is independent research funded by a UK NIHR Cochrane Programme Grant (133131). The views expressed in this publication are those of the review authors and are not necessarily those of the National Health Service, the NIHR, or the UK Department of Health.

## DIFFERENCES BETWEEN PROTOCOL AND REVIEW

- Title changed from "Synbiotics for preventing necrotising enterocolitis in preterm infants" to "Synbiotics to prevent necrotising enterocolitis in very preterm or very low birth weight infants".
- The protocol specified the population of interest as very preterm and VLBW infants in order to enhance applicability to those infants at high risk of developing NEC and associated complications. Some included trials included infants born up to 34 to 35 weeks' gestation. We included these trials provided most participants were very preterm and VLBW infants.
