## Household overcrowding definition

Household overcrowding is, in general, defined as a condition where the number of individuals occupying a dwelling exceeds the capacity of the dwelling space available. A number of definitions and metrics have been used to define overcrowding.<sup>1,2</sup> The most notable are: 1) the UN Habitat where overcrowding occurs when there are more than two people per habitable room (excluding bathrooms but including kitchens and living rooms)<sup>3</sup> 2) the United States Department of Housing and Urban Development (HUD) considers a household overcrowded if more than one person shares a room<sup>1</sup> and 3) the UK government defines a household as overcrowded if it has fewer bedrooms than it needs to avoid undesirable sharing, based on the age, sex and relationship of household members.<sup>4</sup> In the current study, we defined and created a binary outcome indicator of overcrowding as a ratio of individuals to sleeping rooms/spaces higher than two,<sup>5</sup> referred to as person-per-room (PPR).

## Household overcrowding data

### 2.1 Data extraction

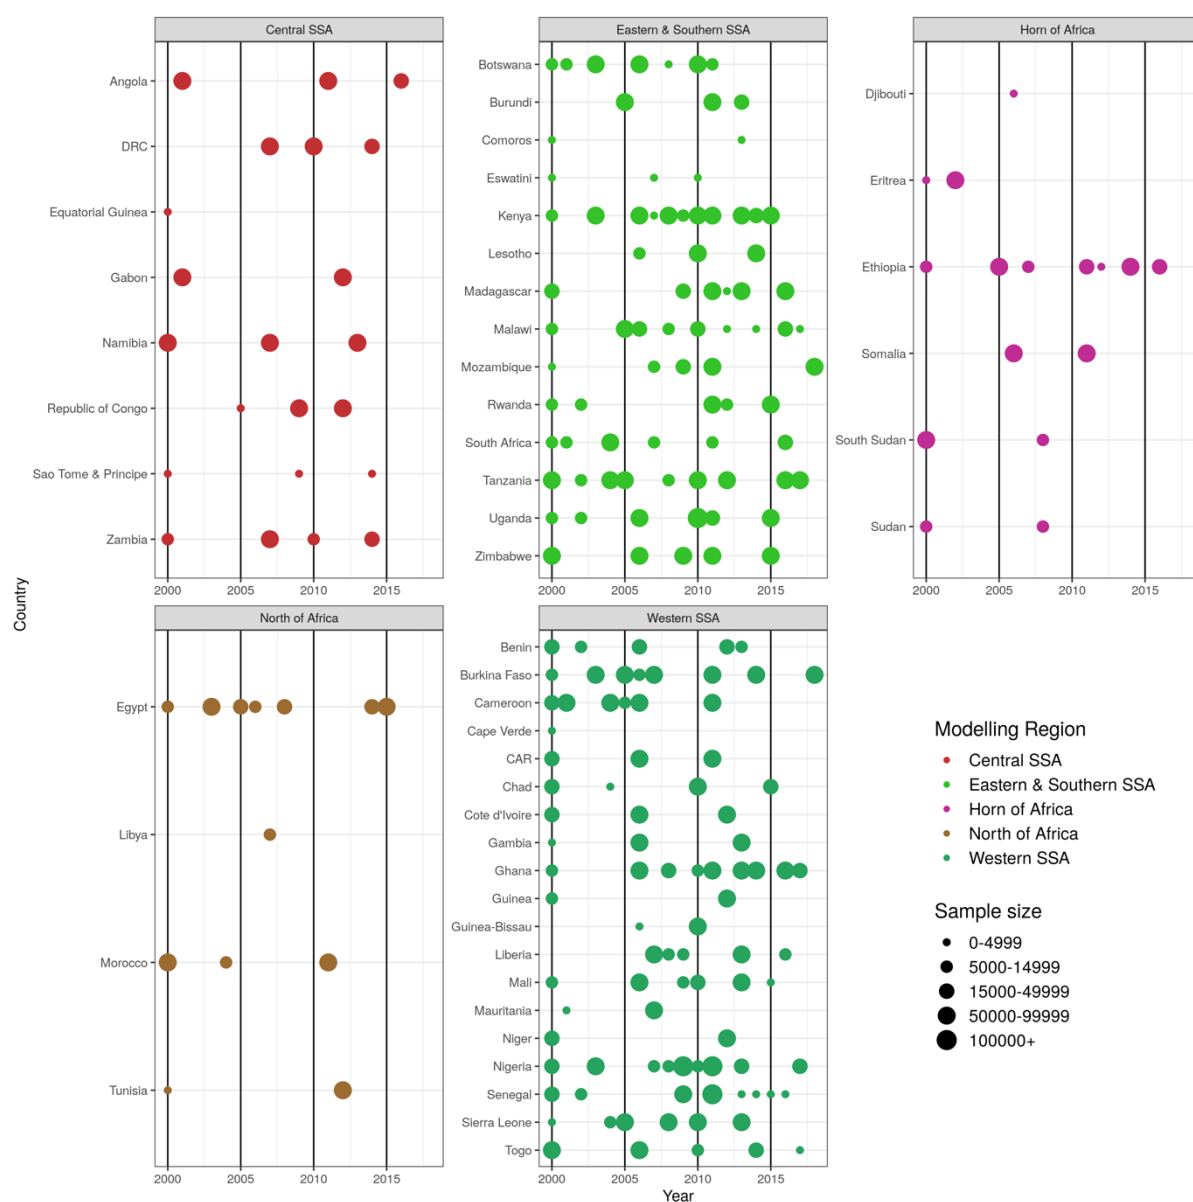

We assembled 386 surveys (USAID's Demographic Health Surveys (DHS), UNICEF's Multiple Indicator Cluster Surveys (MICS), IPUMS' population censuses and other country specific surveys) with information on household size and/or number of habitable rooms in a household based across Africa. Of these, 287 surveys had usable information from which data were extracted, covering 78,695,991 households between 2000 and 2018, from 51 African countries (Figures S1 and S2). Details of the surveys included in the analysis can be found in table S1. We extracted data on the number of habitable rooms in each household and the number of people reported to have slept in the house the night before the survey. Only surveys linkable to sub-national locations (either longitudes and latitudes or administrative divisions) were extracted. The geostatistical model utilised point locations directly and administrative divisions were linked to polygons in shapefiles, which were resampled to point locations, see Section 2.2 below. Shapefiles were obtained from the Food and Agriculture Organisations Global Administrative Unit Layers (GAUL; <http://www.fao.org/geonetwork/>), the Database of Global Administrative Areas (GADM; <https://gadm.org/>), and additional freely available sources online. When required, shapefiles were edited using R and ArcGIS to represent the district boundaries at the time the survey was conducted.

77

78 **Figure S1: Map of data availability for household overcrowding model. Countries with household**  
 79 **surveys contributing to the model are coloured by region.**

**Figure S2: Plot of data availability for household overcrowding by country and year.** The x-axis indicates the year and the y-axis the country in which the survey was undertaken. The size of the points is representative of the number of households in each survey with larger points containing more data, and the colour indicates the modelling region to which that country belongs.

**Table S1: Surveys included in the household overcrowding model.**

## 2.2 Polygon resampling

The methods for polygon resampling are depicted in figure S3. For each polygon we cropped a raster of the WorldPop global population estimates<sup>6</sup>, with a cell area of 5 x 5–km at the equator, to that area (figure S3A). We sampled 10,000–point locations (longitude and latitude of the cell centroid) from each polygon, with a sampling probability proportional to the cell population (figure S3B). K-means clustering was then applied to the point locations, so that there was one cluster per 1,000 raster cells within the polygon. Each cluster was then assigned an integration weight proportional of the number of point locations that were geographically closer to this cluster than any other (figure S3C). The sum of the weights of the point locations for each polygon resampled was equal to one. The resampled, weighted point locations were combined with the actual point data (which were assigned weights of one), and this dataset used as input data for the geostatistical model. In our dataset, over 95% of the data comprised of point level data, with polygon level data contributing less than 5% of the total data used in the analysis.

**Figure S3: Polygon resampling.** A pictorial representation of polygon resampling methods using k-means clustering. a) a raster of the total population cropped to the polygon to be resampled; b) 10,000–point locations sampled with a probability based on the cell population; c) k-means clustering applied to the point locations in (b), the size of the point represents the integration weight; (figure from Golding et al. 2017<sup>7</sup>).

## 2.3 Data preparation

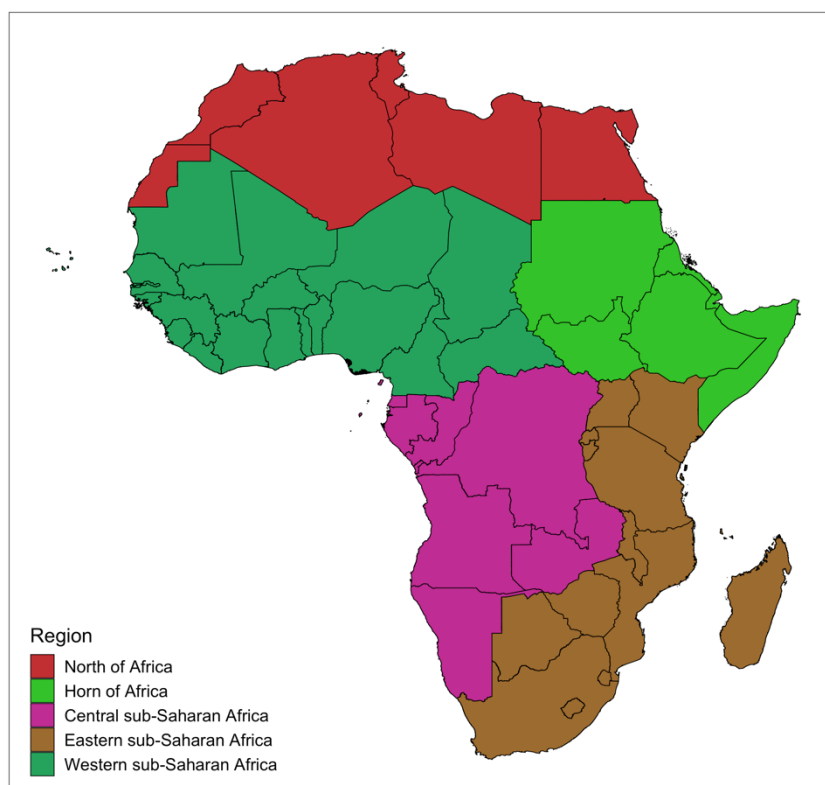

The resampled, weighted point locations were linked to the data for that polygon and added to the data linked to actual point locations which were assigned a weight of one. This data was curated and used in the geospatial model. Data were collapsed to one data point per point location per year. Household overcrowding was defined following WHO guidance as having more than 2 people per habitable room<sup>8</sup>.

## Household overcrowding model

We fit a two-stage Bayesian binomial hierarchal model (see Section 3.3) to estimate the proportion of household overcrowding for each 5 x 5–km pixel for the 54 African countries. The model was fit separately for each region (figure S4) to improve computational stability and to incorporate overcrowding pattern differences between regions, and to allow modelling as well as assessment of differing effects and covariates' influence (see below,

covariates selection). Data for island countries was restricted to Madagascar, Cape Verde, Sao Tome & Principe islands and Comoros.

*Figure S4: Geographical regions for the model of household overcrowding.*

### 3.1 Covariate selection

The covariates that were chosen to inform the household overcrowding proportions were selected based on social-economic/environmental plausibility and importance in the model. Covariates were checked for correlation using the Pearson correlation coefficient, if one of any pair of covariates had an  $r^2 > 0.8$  this was dropped from the analysis. covariates were then normalised by subtracting the mean from each value and dividing them by the standard deviation, resulting in all covariates having a mean of 0 and a standard deviation of 1. This is considered important in penalised regression models as it puts the regression coefficient onto the same scale and allows for the comparisons of covariates. Covariate selection was based on their importance in the child models and their impact on the predictive performance of the model. Final covariate selection was based on those informing the models with the best predictive validity. The final model was informed by those with the best out-of-sample metrics after running the model with five-fold cross-validation and covariates. The selected covariates are displayed in table S2 and figure S5 for each modelling region.

### 3.2 Stacked ensemble model

In order to capture the effects of the covariates, we employed a stacked ensemble model<sup>9</sup>. This modelling strategy allows covariate selection, captures potential non-linear effects and accounts for interactions between covariates, while improving the predictive power over standalone models. For each region, we fit three different child models namely boosted regression trees (BRT), generalised additive models (GAM) and penalised regression model (elastic net), using five-fold cross-validation to produce out-of-sample predictions for each data point. The BRT, a decision tree-based machine learning algorithm, was fit using “xgboost” and the “caret” package version 6.085. A grid of potential model parameters were trialled and the final model fit on parameters resulting in superior predictive performance. The GAM models were fit using the “mgcv” package version 1.8.31, with smoothing terms applied to the covariates using thin plate regression splines. E-net is a penalised regression model which incorporates both Lasso (L1) and Ridge (L2) regularisation as was fit using the “glmnet” package version 3.0.2, setting the  $\alpha$  to 0.5 and the  $\lambda$  to the minimum value within one standard deviation of the  $\lambda$  of the best performing model. The estimates from the stacked ensemble model were then used as the explanatory covariates in the subsequent geostatistical model presented in Section 3.3.

\*sub-Saharan Africa

Figure S5: Model covariates selection for each modelling region.

### 3.3 Geostatistical model

#### 3.3.1 Model specification

To estimate the proportion of household overcrowding in each 5 x 5-km pixel in Africa we fit a spatially and temporally explicit binomial Bayesian hierarchical generalised linear model (GLM). We modelled the logit

probability of a household being overcrowded,  $p_i$ , using a GLM with the out-of-sample predictions from the stacked ensemble model,  $X_i$  which was used as the explanatory covariates with the coefficients,  $\beta$ , constrained to sum up to one. A term for the residual spatial and temporal error was included,  $\epsilon_{GP}$ ; together with an independent nugget effect,  $\epsilon_i$ ; and a Gaussian country level random effect,  $\epsilon_C$ , to allow for differences in household structure and composition, as well as housing policies' effects; and a Gaussian survey level random effect,  $\epsilon_s$ , to account for biases and reporting inaccuracies.

The residual spatial and temporal error was modelled as a three-dimensional Gaussian process with a covariance matrix as the *Kronecker* product of spatial covariance ( $\mathbf{K}_{space}$ ) and temporal covariance ( $\mathbf{K}_{time}$ ). Spatial covariance was modelled as a stationary Matérn function<sup>10</sup> and temporal covariance as an autoregressive order 1 (AR1) function.

$$N_i^+ \sim \text{Binomial}(p_i, N_i)$$

$$\text{logit}(p_i) = \alpha + \mathbf{X}_i\beta + \epsilon_C + \epsilon_S + \epsilon_i + \epsilon_{GP}$$

$$\epsilon \sim GP(0, \mathbf{K}_{space} \otimes \mathbf{K}_{time})$$

$$\mathbf{K}_{space} = (2^{\nu-1}\Gamma(\nu))^{-1}(\kappa\mathbf{D})^\nu K_\nu(\kappa\mathbf{D})$$

$$\mathbf{K}_{time_{k,l}} = \rho^{|t_k - t_l|}$$

### 3.3.2 Spatial Mesh creation

A finite element spatial mesh is required to fit the stochastic partial differential equation (SPDE) approximation, used to model the spatial–temporal error. We used smoothed polygon boundaries for the modelled regions as templates for the meshes. We created inner triangles for the mesh with a maximum edge length set to 0.3 degrees and the outer buffer triangles maximum edge length set to 5 degrees. Figure S6 shows the mesh for the Central sub-Saharan Africa region. The spatial mesh was uniform for all modelled regions.

**Figure S6: Finite element mesh for the Central sub-Saharan Africa region.**

### 3.4 Model fitting and validation

The models were fit using Integrated Nested Laplace Approximations (INLA)<sup>11</sup> in the R statistical software environment (R version 3.5.0)<sup>12</sup>. The spatial-temporal error was modelled using stochastic partial differential equation (SPDE) approximation with 1,000 draws of the model posterior. These were used to calculate the median, mean and 95% uncertainty intervals (UI) for the probability of household overcrowding for each 5 x 5-km pixel. The draw-level estimates were aggregated to the district, state and national levels, calculating the median, mean and 95% uncertainty intervals for each of these levels.

In order to inform how accurate the model predictions are where little or no data is present, we performed model predictive performance. Five-fold cross validation and computed out-of-sample predictive performance measures were performed (root mean square error (RMSE) and coefficient of determination ( $R^2$ )).

The models were validated following these steps:

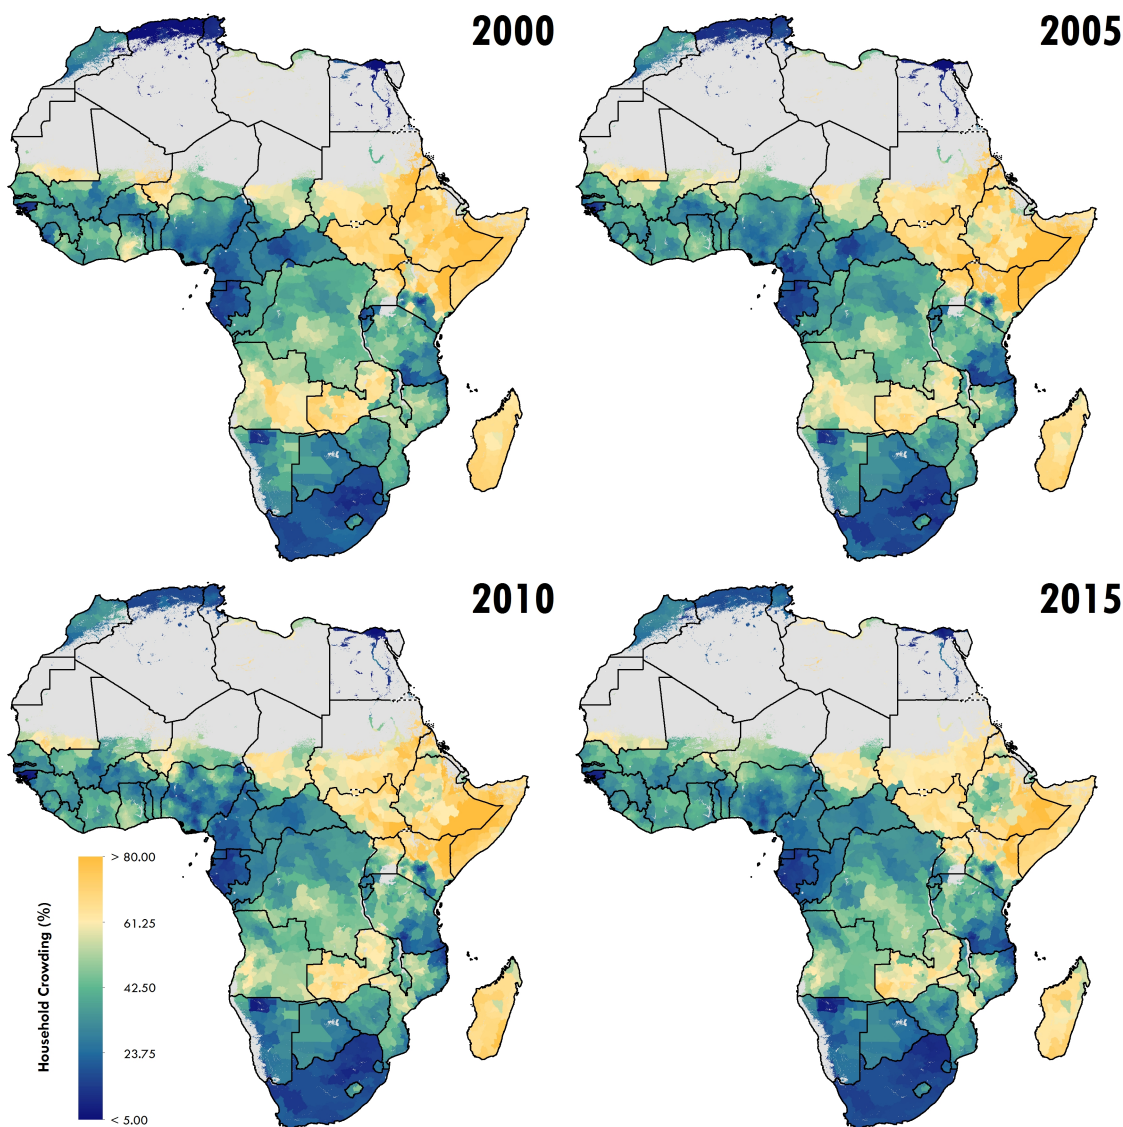

- a) Available surveys were assigned to one of five random folds;
- b) Five datasets were created holding out one-fold of data from each dataset and fitting the model on each of these datasets using the final model specifications. Thus, creating an out-of-sample prediction for each data point;

c) The  $R^2$  and RMSE of the input data points and the mean out-of-sample prediction were computed to show the predictive validity of the model. These metrics were computed for each level (district, state and national level metrics are presented in figures S11 - S12).

## Household overcrowding model results

### 4.1 Model results

Household overcrowding proportions were estimated from 1,000 draws of the model posterior for each 5 x 5 km pixel in Africa for each year, from 2000 to 2018. The estimates were aggregated to the national (administrative level 0), state (administrative level 1) and district (administrative level 2) levels. Given policy decisions are often made at the district administrative level we present the estimates at this spatial resolution; this also provides identification of fine spatial trends without focusing on small populations. Figure S7 shows the district administrative level estimates of household overcrowding aggregated to five-year blocks throughout the study period (2000 - 2015).

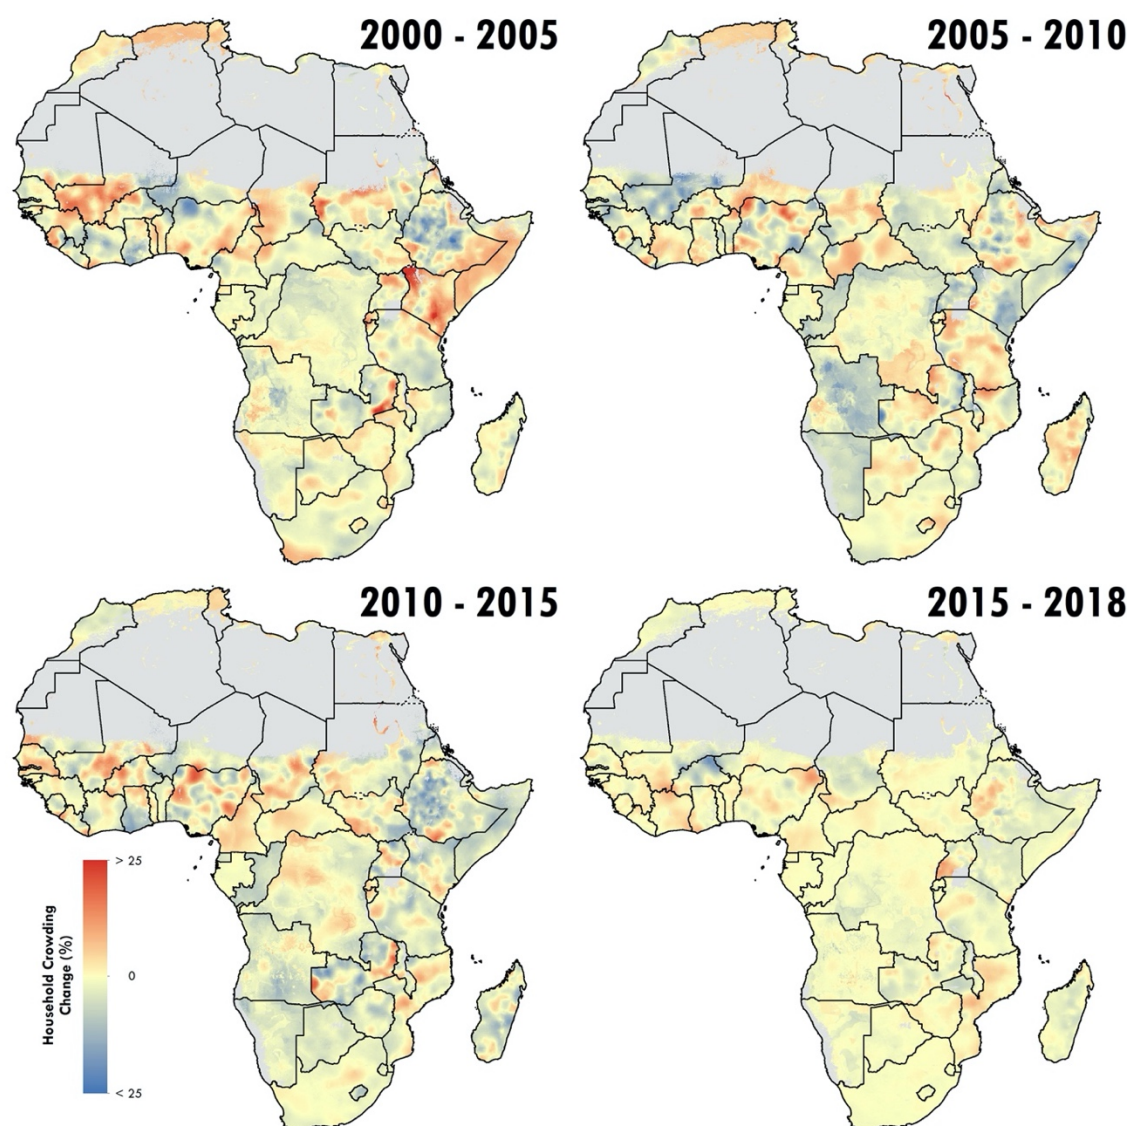

**Figure S7: Five yearly estimates of the proportions of household overcrowding in Africa, at the administrative level 2 (district).** Estimates for (a) 2000; (b) 2005; (c) 2010; (d) 2015. Pixels (1 x 1 km resolution) with populations of less than 10 are masked out in grey.

There has been very little change in household overcrowding over the study period across the Central-, Western-, Eastern & Southern- sSA. The Horn of Africa region, Zambia and Madagascar all recorded consistently high household overcrowding proportions. In contrast, a decrease in overcrowding proportions were estimated for

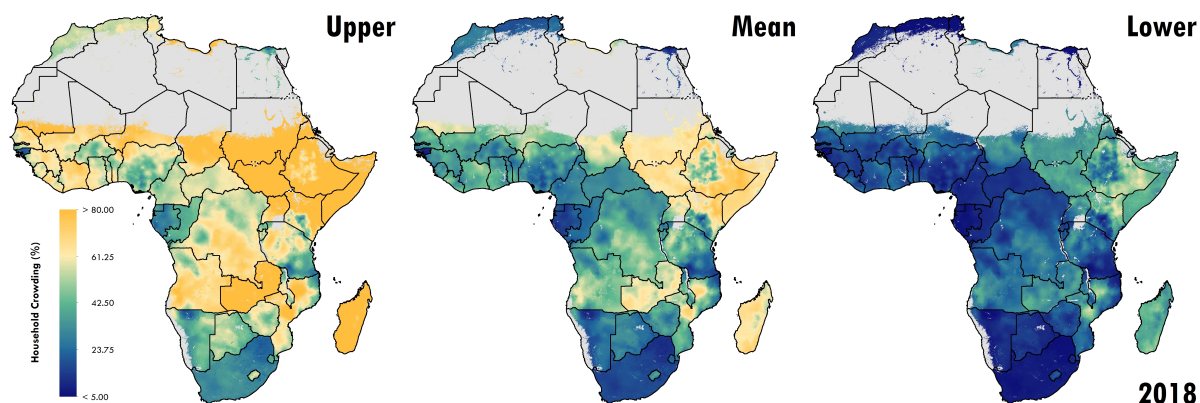

a number of countries: Ethiopia, down on average 17% (from 72% [95% UI: 67 - 77%] in 2000 to 55% [48 - 62%] in 2018); Angola decreased by 13% (from 56% [49 - 62%] to 43% [36 - 49%]) and Zambia decreased by 6% (from 63% [56 - 69%] to 57% [47 - 66%]); and (figure S8). Household overcrowding temporal trends showed an increase in the North of African countries: Algeria increased on average 14% (from 5% [95% UI: 2 - 11%] in 2000 to 19% [95% UI: 9 - 36%] in 2018) and Tunisia increased 11% (from 11% [95% UI: 3 - 25%] to 22% [95% UI: 9 - 42%]). Household overcrowding remained relatively low in South Africa throughout the study period, with an average of 15% [95% UI: 12 - 20%] in 2018.

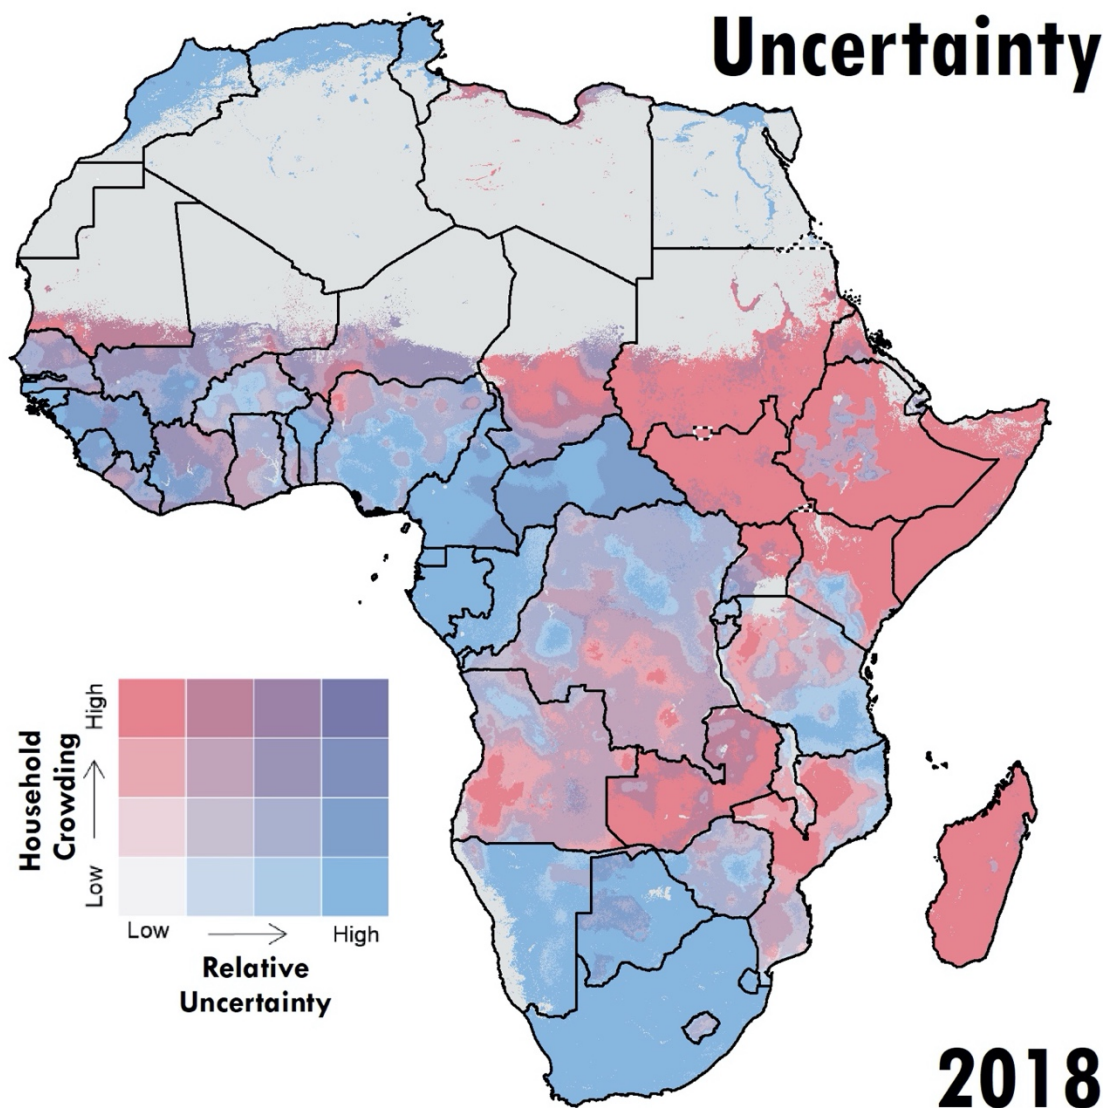

**Figure S8: Five yearly estimates of change in the proportions of household overcrowding in Africa, at 5 x 5 km pixel level.** Estimates for change (a) 2000 - 2005; (b) 2005 - 2010; (c) 2010 - 2015; (d) 2015 - 2018. Pixels (1 x 1 km resolution) with populations of less than 10 are masked out in grey.

We are able to use the model-based geospatial framework to model uncertainty quantification as shown in figure S9 where the lower, mean and upper uncertainty results are mapped (where (a) shows the 2.5 percentile, (b) the mean, and (c) the 97.5<sup>th</sup> percentile of the 1,000 draws of the model posterior). The 95% uncertainty range estimates are relatively small for Central-, Western-, Southern- sSA and North of Africa regions, indicating that the model is confident in predicting household overcrowding in these parts of Africa. However, the model estimates a relatively large range for the 95% uncertainty interval on Madagascar, Zambia, parts of Mozambique and the Horn of Africa regions as depicted by the density of colour in the upper 95% UI in figure S9.

**Figure S9: Estimates of the household overcrowding proportions in Africa for 2018 with the mean and upper and lower 95% uncertainty intervals.** A) estimates of the upper 95% uncertainty value; b) mean estimates; c) estimates of the lower 95% uncertainty value. Pixels (1 x 1 km resolution) populations of less than 10 are masked out in grey.

Figure S10 compares the proportions of household overcrowding from low to high, versus relative uncertainty from the modelling, as measured by the ratio of 95% uncertainty interval to the mean in 2018. To quantify the level of household overcrowding we took the ratio of uncertainty intervals to the proportion of household crowding estimates in each district, and displayed this in relation to overcrowding proportion estimates. High relative uncertainty coupled with low household overcrowding proportions were observed in South Africa, Namibia, Botswana, Republic of Congo, Cameroon, CAR, Gabon, Equatorial Guinea, Guinea, Sierra Leone, Egypt, Tunisia, Algeria and Morocco. High overcrowding proportions and low relative uncertainty were observed in Madagascar, Zambia, Mozambique, Kenya, Somalia, Uganda, Ethiopia, South Sudan, Sudan, Southern parts of Chad and South Western parts of Angola. High household overcrowding proportions were observed with high uncertainty in most parts of Senegal, Mali, Niger, Liberia, Cote d'Ivoire, Ghana, Nigeria, Lesotho and DRC.

**Figure S10: Overlapping population-weighted quartiles of household overcrowding and relative uncertainty in 2018.** Relative uncertainty was computed as the ratio of the 95% uncertainty intervals and household overcrowding proportion for each pixel. The lowest quartile of household overcrowding is white, and the highest is dark pink. The lowest quartile for uncertainty is white and the highest is blue. These colours overlap such that areas coloured purple have both high overcrowding proportions and high relative uncertainty. Pixels (1 x 1 km resolution) with populations of less than 10 are masked out in grey.

#### 4.2 Model validation

Out-of-sample model predictions were calculated as validation metrics, these were aggregated to the national level together with household overcrowding proportions from each survey from the input dataset. In order to understand the deviance of the model data from the input data we computed the root mean square error (RMSE) together with the  $R^2$  to show the coefficient of determination between the data and model estimates. While the full model was correlated to the input data with an  $R^2$  of 0.87 and an RMSE of 0.11; the predictive validity varied by region (table S3 and figures S12a - e) performing best in the Central sSA, North of Africa and Eastern & Southern sSA regions; and struggled for predictive validity in Western sSA, Eastern sSA and the Horn of Africa regions.

**Table S3: In- and out-of-sample metrics for the five-fold cross validation models on household overcrowding.**

Modelling region	In sample		Out of sample	
	RMSE	Corr* (R <sup>2</sup> )	RMSE	Corr* (R <sup>2</sup> )
Overall	0.08	0.95	0.11	0.87
Eastern sub-Saharan Africa	0.09	0.86	0.12	0.58
Western sub-Saharan Africa	0.08	0.74	0.12	0.27
Central sub-Saharan Africa	0.02	0.99	0.06	0.81
North of Africa	0.01	0.97	0.03	0.78
Horn of Africa	0.06	0.76	0.10	0.17

\*Coefficient of determination.

**Figure S11: Validation plots for the model of household overcrowding proportions.** a) Left scatter plot representing the mean proportion of household overcrowding for each survey, at the national level, against the in-sample predicted proportion of household overcrowding for that country-year; b) Right scatter plots of the mean proportion of household overcrowding for each survey, at the national level, against the out-of-sample predicted proportion of household overcrowding for that country based on five-fold cross validation.

**Figure S12: Validation plots for the model of household overcrowding for each modelling region.** Each plot shows the mean household overcrowding proportion from each survey, at the national level, against the out-of-sample predicted household overcrowding proportion for that country–year

based on five-fold cross-validation. a) Central SSA; b) Western SSA; c) Eastern SSA; d) North of Africa; e) Horn of Africa.

### Gather Checklist

This study was conducted in line with the Guidelines for Accurate and Transparent Health Estimates Reporting (GATHER).<sup>13</sup>

**Table S4: GATHER Checklist.** A checklist identifying each point of the Guidelines for Accurate and Transparent Health Estimates Reporting and whether they are covered in this study.

Item #	Checklist item	Reported on page #
<b>Objectives and funding</b>		
1	Define the indicator(s), populations (including age, sex, and geographic entities), and time period(s) for which estimates were made.	6, 9, S1
2	List the funding sources for the work.	3, 22
<b>Data Inputs</b>		
<i>For all data inputs from multiple sources that are synthesized as part of the study:</i>		
3	Describe how the data were identified and how the data were accessed.	7, 8, S3–S5
4	Specify the inclusion and exclusion criteria. Identify all ad-hoc exclusions.	8, S3
5	Provide information on all included data sources and their main characteristics. For each data source used, report reference information or contact name/institution, population represented, data collection method, year(s) of data collection, sex and age range, diagnostic criteria or measurement method, and sample size, as relevant.	7–9, S6–S67
6	Identify and describe any categories of input data that have potentially important biases (e.g., based on characteristics listed in item 5).	8
<i>For data inputs that contribute to the analysis but were not synthesized as part of the study:</i>		
7	Describe and give sources for any other data inputs.	7, 8, S66 – S67
<i>For all data inputs:</i>		
8	Provide all data inputs in a file format from which data can be efficiently extracted (e.g., a spreadsheet rather than a PDF), including all relevant meta-data listed in item 5. For any data inputs that cannot be shared because of ethical or legal reasons, such as third-party ownership, provide a contact name or the name of the institution that retains the right to the data.	S6 – S67
<b>Data analysis</b>		
9	Provide a conceptual overview of the data analysis method. A diagram may be helpful.	S68 – S69
10	Provide a detailed description of all steps of the analysis, including mathematical formulae. This description should cover, as relevant, data cleaning, data pre-processing, data adjustments and weighting of data sources, and mathematical or statistical model(s).	7 – 9, S65 – S70
11	Describe how candidate models were evaluated and how the final model(s) were selected.	8 – 9, S70
12	Provide the results of an evaluation of model performance, if done, as well as the results of any relevant sensitivity analysis.	S73 – S77
13	Describe methods for calculating uncertainty of the estimates. State which sources of uncertainty were, and were not, accounted for in the uncertainty analysis.	8 – 9, S70
14	State how analytic or statistical source code used to generate estimates can be accessed.	21
<b>Results and Discussion</b>		
15	Provide published estimates in a file format from which data can be efficiently extracted.	21
16	Report a quantitative measure of the uncertainty of the estimates (e.g., uncertainty intervals).	10 – 15, S70 – S74

17	Interpret results in light of existing evidence. If updating a previous set of estimates, describe the reasons for changes in estimates.	12 - 16
18	Discuss limitations of the estimates. Include a discussion of any modelling assumptions or data limitations that affect interpretation of the estimates.	15
