We have shown in a pilot randomised controlled study [SNAP-HT [4]; REC 14/SC/1316] that blood pressure self-management during the post-partum period after hypertensive pregnancies, results in lower blood pressure after six months; even when medication has been stopped. We now want to assess whether this blood pressure reduction can be reproduced in a larger, randomised, single-blinded study and whether the blood pressure lowering has additional benefits in terms of other cardiovascular and cerebrovascular changes known to occur in women who have had a hypertensive pregnancy. We therefore plan to run a trial of self-management in the post-partum period, using updated Blue-tooth® enabled blood pressure monitoring coupled to physician-assisted dose titration to further advance the self-management aspect of the intervention. The physicians will be specialist clinicians who form part of the research team. We will measure additional structural and functional end organ differences, using magnetic resonance imaging of the brain and heart as well as echocardiography and retinal imaging. This will provide insight into the impact of post-partum blood pressure control on the maternal cardiovascular system and how this associates with blood pressure changes. Together, these studies will help refine future intervention strategies in this cohort of patients.

3. Synopsis

Trial Title	Physician Optimised Post-partum Hypertension Treatment trial		
Internal ref. no. (or short title)	POP-HT		
Trial registration	Registered on clinicaltrials.gov (NCT04273854)		
Sponsor	University of Oxford Clinical Trials and Research Governance Clinical Trials and Research Governance Joint Research Office 1 st Floor, Boundary Brook House, Churchill Drive Headington, Oxford, OX3 7GB Email: ctrg@admin.ox.ac.uk		
Funder	British Heart Foundation Clinical Research Training Fellowship (BHF Grant number FS/19/7/34148)		
Trial Design	Prospective Randomised Open Blinded End-point (PROBE)		
Trial Participants	Women of child-bearing age 18years or over with a diagnosis of pre-eclampsia or gestational hypertension as defined by NICE guideline NG 133 (2019 update of CG107), and requiring anti-hypertensive medication at the point of hospital discharge		
Sample Size	220 enrolled participants with 1:1 randomisation Sub-study: 20 normotensive postnatal women		
Planned Trial Period	31/12/19-01/12/30		
Planned Recruitment period	31/12/19- 31/08/21		
	Objectives	Outcome Measures	Timepoint(s)

Primary	To compare postpartum diastolic BP in the intervention arm to the control arm	24 hour average diastolic BP measured by assessed by SPACELAB 90217 24hr Ambulatory blood pressure monitoring (ABPM)	6-9 months postpartum
Secondary	To compare the effect of the intervention on cardiovascular, cerebrovascular and vascular phenotypes	<p>BP based</p> <p>a) 24 hr average systolic blood pressure assessed by SPACELAB 90217 24hr ABPM</p> <p>b) Mean diurnal diastolic blood pressure assessed by SPACELAB 90217 ABPM</p> <p>c) Mean diurnal systolic blood pressure assessed by SPACELAB 90217 ABPM</p> <p>d) Mean nocturnal diastolic blood pressure assessed by SPACELAB 90217 24hr ABPM</p> <p>e) Mean nocturnal systolic blood pressure assessed by SPACELAB 90217 24hr ABPM</p> <p>f) Mean bedside diastolic blood pressure measured during study visit (mean of 2+3)</p> <p>g) Mean bedside systolic blood pressure measured during study visit (mean of 2+3)</p> <p>Cardiac MRI</p> <p>h) Left ventricular (LV) mass indexed to end-diastolic volume and body surface area (BSA)</p> <p>i) LV EDV indexed to BSA</p> <p>j) LV wall thickness – septum, posterior and RWT</p> <p>k) LA volume indexed to BSA</p> <p>l) Right ventricular (RV) mass indexed to end-diastolic volume and body surface area (MRI)</p> <p>m) RV EDV indexed to BSA</p> <p>n) RA volume indexed to BSA</p> <p>o) LV ejection fraction (EF) & RV EF</p> <p>p) LV and RV stroke volumes indexed to BSA</p> <p>q) Myocardial fibrosis</p> <p>r) ECV (extra-cellular volume)</p> <p>Echo</p> <p>s) LV Diastolic function: E/E' average, E/A ratio, E deceleration time</p> <p>t) Global longitudinal strain (GLS)</p> <p>u) LV systolic function (EF by Biplane Simpson's)</p> <p>v) LA volume by Biplanar assessment</p> <p>Vascular:</p> <p>w) Pulse wave velocity</p> <p>x) Augmentation index</p> <p>y) Aortic BP</p> <p>z) Aortic distensibility (MRI)</p>	<p>Week 6 and 6-9 months for the 24 hr ABPM</p> <p>Baseline, week 1, week 6 and 6-9 months for the bedside blood pressures</p> <p>For Cardiac MRI at 6-12 months post-partum</p> <p>At baseline and at 6-12 months post-partum for Echo outcome measures</p> <p>PWV, Aortic BP and AI at baseline and at 6-12 months</p> <p>Aortic distensibility at 6-12 months</p>

		<p>Cerebrovascular</p> <p>aa) Total white matter hyperintensity volume</p> <p>bb) Cerebral blood flow</p> <p>cc) Mean vessel thickness of the middle and posterior cerebral arteries and internal carotid artery</p> <p>Retinal</p> <p>dd) the corrected central retinal arteriolar equivalent</p> <p>ee) the corrected central retinal venular equivalent</p> <p>ff) corrected central retinal arteriolar equivalent/corrected central retinal venular equivalent ratio.</p>	<p>6 -12 months post-partum for all Brain MRI measures.</p> <p>6-12 months postpartum for all retinal measures</p>
Tertiary:	<p>To explore in-vitro vascular function in a sub-study of 20 women</p> <p>To explore presence/absence of kidney injury and fibro-inflammatory status</p> <p>Quality of life assessment</p> <p>Participant experience: assessment of individual experience following intervention</p>	<p>Exercise Echo</p> <p>Exercise ejection fraction (echo) at 50% of peak workload during a bicycle cardio-pulmonary exercise test (CPET)</p> <p>Exercise LA volume at 50% peak workload</p> <p>CPET</p> <p>VO2 at VT1</p> <p>Assessment of endothelial cell function and circulating biomarker levels associated with vascular angiogenesis and inflammation in normotensive and hypertensive women to determine if BP improvement can affect vascular function</p> <p>T1 mapping of the kidneys</p> <p>EQ-5D-5L health questionnaire results</p> <p>Qualitative semi-structured interviews in subset of individuals</p> <p>Readmission number in each arm</p>	<p>6-12 months postpartum</p> <p>6-12 months postpartum</p> <p>From baseline to 6-12 months postpartum</p> <p>6-12 months postpartum</p> <p>Baseline, week 1, week 6 and 6-12 months postpartum</p> <p>6-12 months postpartum</p> <p>0-12 months postpartum</p>

	Number of readmissions in intervention vs control arm	Number and frequency of side-effects reported (intervention via the app and control during follow up calls/SMS)	0-12 months postpartum
	Side-effect impact		
Intervention(s)	The intervention will consist of physician-optimised self-management of post-partum BP. Women will follow a 'smartphone' app-based algorithm for medication titration, which will provide individualised dose titration advice. This is overseen and any change is approved by physicians who review the uploaded readings and respond to tele-monitored abnormal readings in a timely fashion.		
Comparator	The control arm will be managed as per usual NHS-led care with assessment by their own health care professionals and adjustment of medications as required. The BP of this group will be monitored and recorded at the same time-points and in the same manner as the intervention arm as with all other secondary outcome measures.

76

77

5. Background and rationale

78

Hypertensive disorders of pregnancy affect ~one in 10 pregnancies, which equates to >80,000 women per year in the UK [1]. Hypertension can persist post-partum but in many women has returned to the normal range within 6 months. As a result, the post-partum period has traditionally been considered a low risk period[2] but this time can be accompanied by rapid and often unpredictable changes in blood pressure.

81

82

One study showed that 50% of women with pre- eclampsia have persistent significant hypertension on day 5 following delivery [3], with blood pressure control remaining an issue for up to six weeks after childbirth, often requiring multiple medications and careful titration. At the same time, competing postnatal demands on mothers, not least from the new baby, can be associated with poor adherence and/or poor levels of clinical contact. Drug titration can therefore be sporadic exacerbating poorly controlled hypertension. Recently, a randomised controlled pilot study (SNAP-HT) run in Oxford [4] has suggested self-management of blood pressure in the post-partum period, through home blood pressure monitoring combined with a proprietary

83

84

85

86

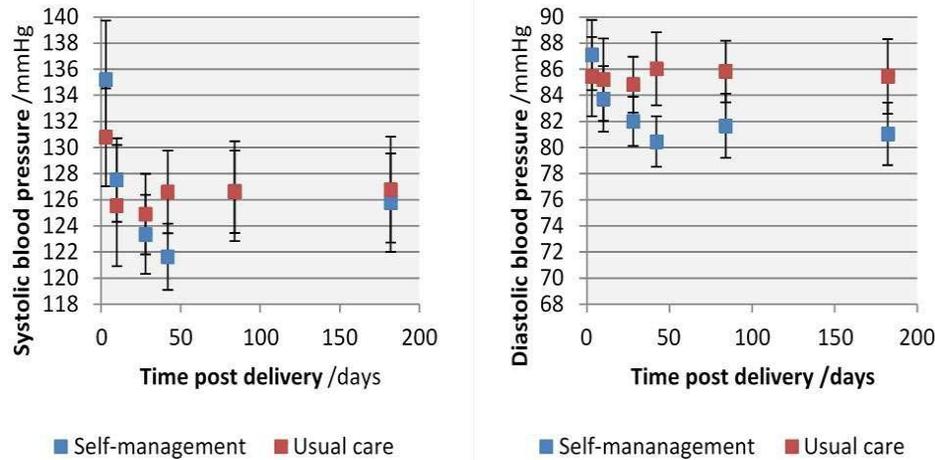

87

88

89 smartphone app in which women entered the BP readings and receive tailored dose instructions, may offer a
90 rational approach to improve blood pressure management in the post-partum period. This approach may be
91 able to overcome some of the problems of poor adherence and drug titration.
92

93

94 High rates of compliance were achieved, and blood pressure control was better in the intervention group, with a
95 mean systolic BP difference of 5.2mmHg and mean diastolic BP difference of 6mmHg, at 6 weeks. However,
96 the most striking finding was that diastolic blood pressure remained a mean 4.5mmHg lower in the intervention
97 group at six months' post-partum; even after the mother had ceased medication [see figure 1 below].

98 **Figure 1:** Comparison of systolic and diastolic BP readings at different time points post-
99 delivery in the treatment vs usual care arms of SNAP-HT

98

99

100 These findings highlight the potential importance of post-partum blood pressure control in determining long-
101 term cardiovascular risk for these women. Risk of higher blood pressure 5 to 10 years after a hypertensive
102 pregnancy is related to blood pressures levels during the first few months post-partum [5] and a recent
103 publication highlighted that a third of women after a hypertensive pregnancy present with chronic hypertension
104 within the next 10 years [6]. Consistent with this, hypertensive disorders of pregnancy are associated with a
105 two-fold increase in risk of subsequent cardiovascular disease [7, 8] and, recent ESC and AHA guidance have
106 advised that such women should be informed of their increased risk [9, 10]. Moreover, levels of blood pressure
107 in the general population are strongly related to long-term risk of cardiovascular disease and are the leading
108 risk factor for loss of disability-adjusted life years (DALYs) in high and low-middle income countries. Every
109 10 systolic/5 diastolic mmHg of blood pressure reduction associates with a ~40% reduction in stroke risk and
110 ~20% reduction in coronary heart disease lifetime risk [11]. Therefore, if the 4.5mmHg improvement in
111 diastolic blood pressure seen in SNAP-HT were maintained long-term, it could correlate to a ~40% lifetime
112 reduction in risk of stroke and ~20% lifetime reduction in risk of coronary heart disease risk.
113

113

114 If improving blood pressure control during the acute post-partum period, as achieved in the treatment arm of
115 SNAP-HT, using a method that is both clinically and cost effective, results in a long term resetting of blood
116 pressure, there is a compelling argument that post-partum blood pressure self-management should be a key part
117 of clinical guidelines [12, 13]. However, several questions require answering to understand the potential
118 clinical translational benefits of the findings in SNAP-HT.
119

119

120 Firstly, is the improvement in blood pressure, which was evident at 6 months' post- partum in SNAP-HT, still
121 evident in the same cohort longer term or do other lifestyle factors known to be relevant to blood pressure
122 potentially overwhelm or exaggerate differences in blood pressure in this cohort over the longer term? This
123 was explored in the NIHR funded SNAP-HT Extension study.
124

124

125 Secondly, can similar blood pressure lowering to SNAP-HT be achieved making use of novel clinical tools?
126 SNAP-HT used a proprietary self-monitoring smartphone app to guide dose titration, which required

127 significant patient involvement in blood pressure measurement, input and response to advised changes in
128 medication. This technology proved promising but as well as testing the blood-pressure lowering
129 reproducibility demonstrate in SNAP-HT through self-management [4], it is also important to start to gather
130 pilot data on whether ‘more-user-friendly’ approaches can reproduce similar differences. For example, ‘Blue-
131 tooth enabled home blood pressure monitors will be used to automate the upload of blood pressure readings to
132 a centralised server reducing the amount of ‘time’ and ‘effort’ women have to contributed themselves during
133 this ‘busy’ time in life with a new-born baby/babies. Women will now have the option of adjusting their own
134 medication based on the uploaded readings which will be reviewed and acted upon by specialist physicians
135 who form part of the research team (medication changes will be based on the NICE NG133 2019 update [14]),
136 Participants can still opt to see their own GP/midwife instead, or in
137 addition, and all usual NHS care will be offered. This Blue-tooth method has been widely used in other studies
138 and notably has been well validated by the OX-VASC group [15, 16].

139

140 Thirdly, does improved post-partum blood pressure control also result in reduced end organ damage in the
141 cardiac, vascular and cerebrovascular systems? A significant finding in women who have had hypertensive
142 pregnancies is early emergence of changes in cardiac, vascular and brain structure and function out of
143 proportion to their cardiovascular risk profile [17-19]. This may explain why this group of women have a
144 disproportionate risk of later cardio-vascular and cerebrovascular disease. It is possible these differences
145 emerge during pregnancy and persist long term, independent of post-partum blood pressure variability but this
146 is not really known and, although the significant cardiovascular adaptations that emerge during complicated
147 pregnancies are known to reverse to some extent during the post-partum period [20-23], an alternative
148 hypothesis it that the long term ‘risk reflects a failure of the cardiac, vascular or cerebral systems to ‘normalise’
149 after pregnancy [24, 25]. Recent data from the C-MORE (Capturing MultiORgan Effects) of COVID-19
150 study, under peer review, has suggested inflammation in the kidneys plays a role in blood pressure control.
151 Given that pre-eclampsia is known to cause cardio-renal dysfunction[26], exploration of the inflammatory state
152 of the kidneys at 6-12 months post-partum has also been added as part of the study to explore this association.

153

154 If improved post-partum blood pressure control can influence cardio-vascular and vascular remodelling it may
155 offer a new approach to modify these long-term end organ changes, in addition to any beneficial effects on
156 blood pressure as demonstrated in SNAP-HT.

157

158 **Description of the population to be studied**

159 We aim to recruit 200 participants to the main study who have had a hypertensive pregnancy and who required
160 anti-hypertensive medication at the time of discharge from hospital (as in the pilot study SNAPHT; REC
161 14/SC/1316) who have capacity to self-manage their blood pressure following discharge from hospital guided
162 by physician-assistance remotely.

163

164 **Safety and Benefits of the study**

165 Data from large multi-centre randomised controlled trials have not suggested any significant risk associated
166 with self-management of essential hypertension [27-29]. We aim to minimise any potential risks due to poor
167 blood pressure control by ensuring women have clear advice regarding when to seek urgent medical help. This
168 will be reinforced by messages from the tele-monitoring service when they submit a blood pressure reading,
169 which is outside the target range. This will direct them where to seek medical attention depending on the
170 severity of the reading. Participants will also be provided with a free telephone number for an advice line that
171 will be answered by one of the specialist physicians who form part of the research team in normal working
172 hours (9-5pm Monday-Friday). Outside of these hours, women will be asked to contact their usual NHS
173 providers for any concerns/symptoms and to submit these via the app. Women in the self-management group
174 will also receive usual blood pressure monitoring and management by their community midwife and GP
175 following their discharge from hospital. However, for safety it is important that participants in this group
176 adhere to the home monitoring schedule. In the first 14 days after birth NICE recommends, that BP is
177 monitored on at least alternate days. Therefore, in the first 2 weeks following discharge, if a participants fail to
178 upload readings via the smart phone app after 24 hours they receive a notification to prompt and remind them.
179 If at 36 hours a reading has still not been submitted the system will trigger the research team to contact
180 participants to encourage them to take a reading, and to explore reasons why readings are not being done.
181 Motivational SMS messages, developed with psychologist input and PPI feedback will also be used. From 14

182 days after delivery until treatment is discontinued, failure to report a blood pressure reading for 5 days will
 183 trigger the research team to contact a participant and if they refuse to engage, they will be withdrawn. If a
 184 participant withdraws / is withdrawn from the study, we will contact their GP/midwife to inform them, in order
 185 to ensure that any on-going care they require is reinstated.

186
 187 In addition, it was also pleasing from the safety viewpoint that there were no SAEs within SNAP-HT [4] and
 188 the pending qualitative analysis was exceedingly positive in favour of empowering this group of women
 189 through self-management.

190
 191 In terms of benefit, not only do we hope to demonstrate reproducibility of improved blood-pressure control in
 192 the intervention arm but furthermore, current national and international guidance for the post-partum care of
 193 pre-eclampsia and gestational hypertension lacks robust, high-quality evidence to guide practice and we hope
 194 to provide data that helps improve this aspect of care. Around 30% of eclamptic fits and over half of strokes
 195 associated with severe pre-eclampsia occur post-partum [3] due to poor home BP control and SNAP HT [4]
 196 demonstrated the feasibility of home blood pressure monitoring and drug titration up to 6 months post-partum.
 197 We also hope that the blood pressure improvement achieved will result in beneficial remodelling of the
 198 cardiovascular and cerebrovascular systems of women who had experienced a hypertensive pregnancy and
 199 mitigate their long-term cardiovascular risk, but even if this is not evident, the data will significantly develop
 200 our understanding of the implications of post-partum blood pressure through the use of sensitive MRI and
 201 vascular measures in the post-partum period.

202 The purpose of the sub study is to provide a reference population of women not affected by hypertensive
 203 disease. In the sub study, healthy postnatal women will undergo measurements of specific characteristics of
 204 blood cells and circulating factors involved in inflammation and endothelial dysfunction. This population will
 205 validate how blood cells and circulating factors vary naturally and may be affected by external factors such as
 206 mode of delivery.

207
 208
 209

6. Objectives and outcome measures

	Objectives	Outcome Measures	Timepoint(s)
Primary	To compare postpartum diastolic BP in the intervention arm to the control arm.	24 hour average diastolic BP measured by assessed by SPACELAB 90217 24hr Ambulatory blood pressure monitoring (ABPM)	6-9 months postpartum
Secondary	To compare the effect of the intervention on cardiovascular, cerebrovascular and vascular phenotypes	BP based a) 24 hr average systolic blood pressure assessed by SPACELAB 90217 24hr ABPM b) Mean diurnal diastolic blood pressure assessed by SPACELAB 90217 ABPM c) Mean diurnal systolic blood pressure assessed by SPACELAB 90217 ABPM d) Mean nocturnal diastolic blood pressure assessed by SPACELAB 90217 24hr ABPM e) Mean nocturnal systolic blood pressure assessed by SPACELAB 90217 24hr ABPM f) Mean bedside diastolic blood pressure measured during study visit (mean of 2+3)	Week 6 and 6-9 months for the 24 hr ABPM Baseline, week 1, week 6 and 6-9 months for the bedside blood pressures

Tertiary:	To explore in-vitro vascular function in a sub-study of 20 women	<p>Exercise Echo Exercise ejection fraction (echo) at 50% of peak workload during a bicycle cardio-pulmonary exercise test (CPET) Exercise LA volume at 50% peak workload</p> <p>CPET VO2 at VT1</p> <p>Assessment of endothelial cell function and circulating biomarker levels associated with vascular angiogenesis and inflammation in normotensive and hypertensive women to determine if BP improvement can affect vascular function</p>	<p>6-12 months postpartum</p> <p>6-12 months postpartum</p> <p>From baseline to 6-12 months postpartum</p>
	To explore presence/absence of kidney injury and fibro-inflammatory status	T1 mapping of the kidneys	6-12 months postpartum
	Quality of life assessment	EQ-5D-5L health questionnaire results	Baseline, week 1, week 6 and 6-12 months postpartum
	Participant experience: assessment of individual experience following intervention	Qualitative semi-structured interviews in subset of individuals	6-12 months postpartum
	Number of readmissions in intervention vs control arm	Readmission number in each arm	0-12 months postpartum
		Number and frequency of side-effects reported (intervention via the app and control during follow up calls/SMS)	0-12 months postpartum
	Side-effect impact		

210

211

Intervention(s)	The intervention will consist of physician-optimised self-management of post-partum BP. Women will follow a ‘smartphone’ app-based algorithm for medication titration, which will provide individualised dose titration advice. This is overseen and any change is approved by physicians who review the uploaded readings and respond to tele-monitored abnormal readings in a timely fashion.
Comparator	The control arm will be managed as per usual NHS-led care with assessment by their own health care professionals and adjustment of medications as required. The BP of this group will be monitored and recorded at the same time-points and in the same manner as the intervention arm as with all other secondary outcome measures.

212

213

214

7. Study design

215

Design

216

The trial is a single centre, Prospective Randomised Open Blinded End-point (PROBE) study. Women who develop hypertensive disorders of pregnancy, which require on-going treatment for blood pressure after birth at the time of discharge, will be randomised to one of two treatment arms: usual care, or self-management of blood pressure. Women will be recruited from the John Radcliffe Hospital and this study will investigate the effectiveness of post-partum physician assisted self-management of blood pressure vs standard care over the first 6 (up to 12) months post-partum.

222

223

On March 17th 2020, the COVID-19 pandemic meant that all research across Oxford University and OUH NHS Foundation Trust had to be halted. Minor amendment 2.0 allowed us to continue follow up of those women already recruited but as of 06/05/2020 and Minor amendment allowed the POP-HT RCT¹ to restart during the COVID-19 pandemic. The investigating team believe it fulfils ‘exception 3’ of the OUH NHS Foundation Trust guidance for research during COVID-19 as the OUH TMA agreed and gave permission for the trial to restart in June 2020. Based on our experience during the follow up of the 18 participants already recruited, it is believed that ongoing recruitment into this trial will allow women in both the intervention and control arm to receive ‘better’ clinical care at a time of huge disruption to normal care. We also believe that this trial will allow the trust to better adhere to the updated Royal College of Obstetrics and Gynaecology (RCOG) guidance on the care of women during COVID-19.

233

234

A few key changes are required to the baseline visit to reduce the risk of COVID-19 transmission for both researchers and the study participants. Appendix F contains a full explanation and rationale for restarting the trial, which has been approved by the RDM Head of Department and submitted to OUH NHS Foundation trust R&D for their approval.

238

239

Main trial setting and participant profile

240

We aimed to recruit 200 participants with 1:1 randomisation. The intervention arm will comprise telemonitored home blood pressure monitoring (including periods of home 24hr ABPM) coupled with physician-assisted self-management. The control arm will receive ‘standard’ levels of NHS care from their GP and midwives and health visitors. All participants will be recruited from the Oxford Women’s Centre at the John Radcliffe Hospital, which sees approximately 25 patients per month with hypertensive pregnancies (demonstrated in a local audit). As a result of COVID-19 an updated power calculation was performed, to assess the possible dilutionary affect that the RCOG guidance on home BP monitoring during the 1st week post discharge could have on the primary trial outcome. Based on this it was decided by the Trial Steering Committee to increase the sample size to 220.

249

250

251

Main study visit and measures

252

A flow chart of the proposed study visits is seen in Appendix A.

253

254

The expected duration of participant involvement will be 6 (up to 12) months from enrolment to study completion and participants will be asked to attend four study visits after their pre-screening and enrolment: baseline, at 1 week, at 6 weeks and at 6-12 months. At times when face to face appointments are restricted due to regulations related to the COVID-19 pandemic, the week 1 and week 6 visits can be done remotely where

255

256

257

258 needed to avoid putting participants at undue risk. The primary outcome will be studied over a narrower time
259 frame of 6-9 months as originally described at the studies outset, even during the COVID-19 pandemic, but a
260 further amendment was approved to allow all BP based primary and secondary outcomes to be done remotely
261 if needed. The other secondary outcomes can then be done over a wider timeframe of 6-12 months to allow
262 participants to safely attend their study visit at the hospital (see table A1 of supplementary material). An
263 optional sub-study involving administration of Gadolinium contrast will be offered as an additional component
264 to the MRI during the final study visit in those women who are not breast feeding. This is part of exploratory
265 work that may feed into a larger future trial.

266
267 Although this study only involved the four visits described above (outlined in appendix A), further contact may
268 be planned to take place over the next 10 years to allow longitudinal follow up of this cohort's blood pressure.
269 Details of any additional follow-up visits will be defined closer to the time, REC approval will be sought for
270 any further amendments to allow additional visits, and additional consent will be sought from the participants
271 to ensure they are happy to continue taking part.

272
273 The study team has used the experiences of patients participating in prior self-management studies to assist
274 with this study design and methodology. This included consulting participants from other related studies done
275 by this group, as well as consulting with some of the investigators from these studies. The participant
276 information sheet, additional information sheet and intervention arm information sheet have also been
277 reviewed by several PPI members who have, or have had, raised blood pressure in pregnancy and it was duly
278 amended in light of their comments.

279 **Blood validation sub-study**

281 We also aimed to recruit 20 normotensive participants as a reference population for endothelial function. These
282 participants will be recruited from the Oxford Women's Centre at the John Radcliffe Hospital. The expected
283 duration of participant involvement will be 6 (up to 12) months from enrolment to study completion and will
284 involve 2 study visits following pre-screening and enrolment. The visits will be identical and include
285 anthropometry, blood pressure measurements and a blood test.

288 **8. Participant identification**

289 **Main trial participants**

290 All participants will be females of childbearing age 18 years or over.

291
292 Inclusion in the trial will require a clinician confirmed diagnosis of either gestational hypertension or
293 preeclampsia defined by NICE NG 133 [14] which requires anti-hypertensive medication to control.

294
295 Gestational hypertension diagnosis requires a BP >140mmHg systolic or > 90mmHg diastolic on >2 occasions
296 after 20 weeks of this pregnancy.

297
298 Pre-eclampsia diagnosis will be defined as per NICE NG 133 [14]:

- 299 • New onset of hypertension (>140 mmHg systolic or over 90 mmHg diastolic) after 20 weeks of
300 pregnancy and the coexistence of 1 or more of the following new onset conditions:
- 301 • Proteinuria (spot urine protein/creatinine over 30 mg/mmol [0.3 mg/mg] or over 300 mg/day or at
302 least 1 g/L ['2 +'] on dipstick testing) or;
- 303 • Other maternal organ dysfunction:
 - 304 ○ Renal insufficiency (creatinine 90 umol/L or more, 1.02 mg/dL); ○ Liver
305 involvement (elevated transaminases [ALT or AST over 40 IU/L] with or without right upper
306 quadrant or epigastric abdominal pain);
 - 307 ○ Neurological complications such as eclampsia, altered mental status, blindness, stroke,
308 clonus, severe headaches or persistent visual scotomata;
 - 309 ○ Haematological complications such as thrombocytopenia (platelet count below 150,000
310 cells/ μ L), disseminated intravascular coagulation (DIC) or haemolysis;

- 311 ○ Utero-placental dysfunction such as fetal growth restriction, abnormal umbilical artery
312 Doppler waveform analysis, or stillbirth.

313
314 Participants fulfilling the above diagnoses will be screened against the inclusion and exclusion criteria below
315 and enrolled if suitable.

316
317 **Inclusion criteria**

- 318 • Participant is willing and able to give informed consent for participation in the trial.
319 • Female, aged 18 years or above.
320 • Clinician confirmed diagnosis of either gestational hypertension or pre-eclampsia defined by NICE
321 (as above).
322 • Requiring anti-hypertensive medication at the point of discharge from secondary care.
323 • Participant has clinically acceptable laboratory results and clinical course post-partum with no other
324 adverse complicating factor requiring prolonged admission post-partum that would make
325 participation unfeasible as judged by the CI. Examples would include stroke sequaleae, ongoing DIC
326 etc.
327 • In the Investigator’s opinion, is able and willing to comply with all trial requirements including
328 ownership of a ‘Smart-phone/Tablet’ and willing to use the smart-phone app if randomised to that
329 arm.
330 • Sufficient competence in English Language to follow the app instructions and partake in the study,
331 as judged by the CI.

332

333 **Exclusion Criteria** (the participant may not enter the trial if ANY of the following apply):

- 334 • Significant renal or hepatic impairment that would affect safe medication titration and adjustment as
335 part of the trial, as deemed by the Investigator.
336 • Scheduled elective surgery (excluding caesarean sections) or other procedures requiring general
337 anaesthesia during the trial.
338 • Participant with life expectancy of less than 6 months.
339 • Any other significant disease or disorder, which, in the opinion of the Investigator, may either, put
340 the participants at risk because of participation in the trial, or may influence the result of the trial, or
341 the participant’s ability to participate in the trial.
342 • Participants who have participated in another research trial involving an investigational product in
343 the past 12 weeks.
344 • An absolute contra-indication to MRI (as per MRI safety questionnaire) precludes the women from
345 having an MRI but they can still participate in the remainder of the study
346 • Women with pre-existing hypertension will be excluded, as this is a separate pathology that would
347 affect the efficacy of the study intervention and affect the primary and secondary outcomes of the
348 study.

349

350 Additional exclusion criteria specific to the Gadolinium sub-study are: •

351 Breast feeding (at time of CMR scan),

- 352 • eGFR <30 ml/minute.

353

354 **Blood validation sub-study**

355 A sub- cohort of normotensive postnatal women will be recruited locally from the postnatal ward in the Oxford
356 Women’s Centre at the John Radcliffe Hospital. 20 normotensive participants will be recruited directly to the
357 sub-study and will not be expected to participate in the main POP-HT study. 20/200 of the main trial
358 participants will also have an additional blood test during their baseline visit as part of the sub study (see
359 section 9.5 for further detail).

360

361 Inclusion Criteria for POP-HT blood validation sub-study

- 362 • Participant is willing and able to give informed consent for participation in the trial.
- 363 • Female, aged 18 years or above.
- 364 • Normotensive (BP 140/90) throughout antenatal and postnatal period

365

366 Exclusion Criteria for POP-HT blood validation sub-study

- 367 • Hypertensive disorder of pregnancy
- 368 • Use of beta blockers such as atenolol or equivalent
- 369 • BMI>35
- 370 • Evidence of cardiomyopathy, inherited cardiac conduction abnormalities, congenital heart disease or
- 371 significant chronic disease relevant to cardiovascular status • Folic acid or folate
- 372 supplementation in the third trimester

373

374

375 9. Protocol procedures

376 Study procedures will initially take place in the Women's centre of the John Radcliffe hospital in Oxford.

377 The procedures for each study visit and the estimated time each will take are listed in appendices B and D.

378

379 The baseline study visit (V1) will be within the maternity care areas. Visits 2 and 3, at weeks 1 and 6
380 respectively, will take place at home, if preferred, or in CCRF at the John Radcliffe hospital, Oxford,
381 depending on participant choice to make things easier for participants at a busy time in their lives. The final
382 study visit at 6 (up to 9 months) will take place in CCRF and OCMR at the John Radcliffe hospital, Oxford.
383 During all home visits, a female chaperone will be made available and wherever possible all echo scanning will
384 be done by female researchers. All visits can be interrupted as needed for mothers to attend to their
385 baby/babies. This option may not be available during exceptional circumstances, including the COVID-19
386 pandemic. See appendix F for more information.

387

388 There are essential and desirable procedures forming part of each study visit (see figure 2) so if time does
389 become an issue, particularly during the longer final study visit, the visit can be shortened by not performing
390 some of the desirable procedures. Although we would like all procedures performed in all visits, some of the
391 secondary outcomes are exploratory and will be used to plan larger validation studies in future and hence the
392 reason they are classed as 'desirable'. The final study visit will conclude with the fitting of a 24 hr blood
393 pressure monitor and week-long activity monitor (wrist worn accelerometer) which participants will then post
394 back in pre-paid and self-addressed envelopes to CCRF.

395

396 Recruitment

397 For the main study:

398 All trial participants will be recruited locally from the Oxford Women's Centre in the John Radcliffe Hospital,
399 Oxford. Screening of notes and an eligibility check can take place in the antenatal period from twenty weeks
400 gestation, when the diagnosis of pre-eclampsia/gestational hypertension can be made as per the NICE
401 NG133[14] definition, up-to the time of discharge post-natally whilst they are receiving clinical care in the
402 Oxford Women's Centre. Screening will be done by the clinical care team looking after the patient.

403

404 Following identification of a potentially eligible patient by the clinical team, a member of the clinical team will
405 provide potential participants with an invitation letter, a participant invitation sheet (PIS) and the additional
406 study information sheet, the latter of which details more about the procedures involved in the longer, final
407 study visit. To avoid the use of paper during the COVID-19 pandemic these will be provided to the participant
408 by the clinical team on a sterile tablet during this period of time and e-mailed to the participant also.

409

410 The clinical team will then follow up by obtaining verbal consent to inform the research team of the potential
411 participant's interest. If verbal consent is given, the research team will then be notified. If this is antenatally, the
412 research team will make contact after at least 24 hours. If this is postnatally, the research team will make
413 contact after >12 hours. When the research team meet the participants, the women will be able to ask questions
414 and talk through any queries with the study team before enrolment is considered. If they remain happy to take
415 part, their medical notes will be screened again by a member of the research team to ensure they are definitely

416 eligible to participate. Antenatally, if a woman fulfils all of the eligibility criteria, the research team will check
417 when the participant will next be visiting for clinical assessment and will aim to obtain written informed
418 consent at that next visit. This will allow at least 24 hours for participants who are antenatal to consider the PIS
419 and invitation letter prior to being consented.

420

421 In exceptional circumstances (including during the COVID-19 pandemic) participants may be given a reduced
422 amount of time to consider participating in the study. Due to expedited discharge processes during the COVID-
423 19 a reduced amount of time (at least an hour) will be given to consider the documentation whilst the pandemic
424 is ongoing. Only a single member of the research team will be admitted to the maternity care areas, wearing
425 level 1 personal protective equipment (PPE). More details of this can be found in Appendix F.

426

427 Posters and flyers will also be displayed in the Women's centre with the research team's contact details to allow
428 screening for eligibility and provision of PIS, invitation letter and additional information sheet if participant's
429 contact us in this way.

430

431 Whilst the study will aim to first approach women antenatally, it may be that they can only be enrolled
432 postnatally in some cases e.g. if they present with pre-eclampsia as an emergency and have to have an
433 emergency delivery, which is not uncommon. In these cases, again the clinical team will provide the
434 aforementioned study documents and obtain verbal consent to refer the women to the research team. Due to the
435 time limitation on their inpatient stay, a reduced period will be given for consideration of the study documents.
436 In this case, a minimum of 12 hours will be given before approaching the potential participant to consider
437 enrolment and consent into the study by the research team. This is to maximise potential enrolment to the
438 study. It will be made clear to the potential participant that they are able to withdraw at any time from the study
439 without giving any reason for withdrawal and without this affecting their clinical care.

440

441 For the blood validation sub-study:

442 Screening for eligibility will be performed by the clinical care team looking after the patient. Following
443 identification of a potentially eligible patient by the clinical team, a member of the clinical team will provide
444 potential participants with an invitation letter and a participant invitation sheet (PIS).

445

446 **Records screening and eligibility assessment**

447 Records screening may occur as early as 20 weeks' gestation once a hypertensive disorder of pregnancy has
448 been diagnosed. Obstetric records will be screened by the NHS clinical care team to assess eligibility before
449 the potential participant is considered for referral to the research team for possible recruitment.

450

451 If the participant has been screened and enrolled antenatally, the research team will re-screen postnatally to
452 check that they still fulfil the eligibility criteria for the study i.e. That there have been no serious medical
453 complications for the mother or the new-born in the intervening period that precludes their participation and
454 that they still require anti-hypertensive medication postnatally. The team do not intend to deliberately exclude
455 women based on any medical complications but wish to be sensitive to the needs of the participant and avoid
456 overburdening them. It is also vital that women recruited antenatally are given a very clear opportunity to opt
457 out at the postnatal stage in case they have changed their mind and hence it is planned to re-confirm their
458 original consent at this stage.

459

460 Furthermore, patients who have previously not met the inclusion criteria initially may be rescreened later in
461 pregnancy or in the postnatal period should their status change, e.g. if they have only just started on anti-
462 hypertensive medication in the post-natal period. Women with raised blood pressure after birth typically stay in
463 hospital for an average of 2-3 days after birth which should provide adequate opportunity for notes screening of
464 newly identified eligible women, consent at >12 hours later (time reduced during COVID-19 as per protocol
465 amendment –see table A1 of supplementary material) and then a baseline visit for those recruited postnatally.
466 For those recruited antenatally, it will allow time for re-confirmation of eligibility and verbal re-confirmation
467 of consent followed by the baseline visit. Protocol waivers will not be permitted.

468

469 **Informed consent**

470 The participant must personally sign and date the latest approved version of the Informed Consent form(s)
471 before any trial specific procedures are performed. Please see Appendix F for details of how consent will be

472 modified during the COVID-19 pandemic to reduce risk of the paper acting as a vector for transmission of
473 Coronavirus.

474
475 Written and verbal versions of the Participant Information and Informed Consent form(s) will be presented to
476 the participants detailing no less than: the exact nature of the trial; what it will involve for the participant; the
477 implications and constraints of the protocol; the known side effects and any risks involved in taking part. It will
478 be clearly stated that the participant is free to withdraw from the trial at any time for any reason without
479 prejudice to future care, without affecting their legal rights and with no obligation to give the reason for
480 withdrawal.

481
482 Consent will be obtained at the earliest appropriate opportunity after provision of the PIS and invitation letter
483 and discussion with the research team to enable any queries to be addressed. As explained in section 9.1,
484 participants identified postnatally may be enrolled as early as 12 hours after provision of the PIS and invitation
485 letter, but no earlier than this. These participants will have the same opportunity to ask questions. Only then
486 after 12 hours, will the study team re-visit the participant to enrol them and obtain informed consent. For those
487 recruited antenatally they will have the usual 24 hours minimum for consideration of the PIS and invitation
488 letter before being asked to enrol.

489
490 Written Informed Consent will then be obtained by means of participant dated signature and dated signature of
491 the person who presented and obtained the Informed Consent. This study will not involve children, vulnerable
492 adults or adults who lack capacity. The person who obtained the consent must be suitably qualified and
493 experienced, and have been authorised to do so by the Chief Investigator. A copy of the signed Informed
494 Consent will be given to the participant. The original signed form will be placed in the medical notes and a
495 further copy will be retained at the trial site and one given to the participant.

496
497 Additional informed consent will be sought at the final study visit/visit 4 for those participants eligible and
498 willing to enter the gadolinium sub-study.

499

500 **Randomisation**

501 Randomisation will be performed as soon as possible following delivery of the baby/babies, after enrolment
502 and consent, and after the baseline visit. The process of randomisation will involve secure webbased
503 randomisation software (embedded within CASTOR ®) on a 1:1 basis and minimisation will be based on the
504 following two factors:

- 505 • Primary factor agreed on as a surrogate marker of disease severity: Gestational age at the time of
506 presentation with pre-eclampsia/gestational hypertension
- 507 • Receipt of prescription of ACE inhibitor (Enalapril) at time of randomisation.

508

509 Randomisation will be carried out (the generation and concealment of the random sequence) by CASTOR®
510 EDC® proprietary web-based randomisation software. Prior to COVID-19 this was done by a separate member
511 of the CCRF research group, to those investigators performing the baseline visit itself and a un-blinded
512 research assistant will implement this (inform participants) and subsequently instruct on the use of the
513 intervention for those randomised to that arm. However, since the onset of the COVID-19 pandemic: whilst
514 restrictions on visitors remain in place for maternity areas, the randomisation will be done electronically via
515 CASTOR® as before but the same individual doing the visit will inform participants of the arm they are
516 allocated to and instruct them appropriately i.e. the trial changed from blinded to open-label (see blinding
517 section below).

518

519 Prior to COVID, the clinical research manager/research assistant, involved in generating and implementing the
520 randomisation sequence respectively, was not involved in primary or secondary outcome datacollection or
521 analysis at any point. The clinical research manager was also responsible for allocation concealment.
522 Allocation will be concealed using CASTOR EDC® electronic database. After restarting the trial post COVID,
523 allocation was concealed using CASTOR EDC® from those performing the data analysis.

524

525 Both pre and post-COVID Study clinicians giving advice on the telephone help-line based on readings
526 submitted to the app as part of the intervention will only see a number (e.g. POP-HT 004) and initials and there
527 will be no face-to-face communication. To ensure adequate clinical decision-making a limited amount of

528 relevant medical history will be entered onto the POP-HT web-based system for clinicians logging on e.g. Pre-
 529 eclampsia onset at 32 weeks. EMCS. Haemoglobin 72 at discharge following postpartum haemorrhage,
 530 Creatinine 72. No other history of note. To minimise any potential risks from poor blood pressure control
 531 women will receive clear verbal advice and written guidance (in the form of intervention arm information
 532 sheet), and the same advice will be available on the app, regarding when to seek urgent medical help. This will
 533 be reinforced by messages from the tele-monitoring service when participants submit an out-of-range blood
 534 pressure reading.

535

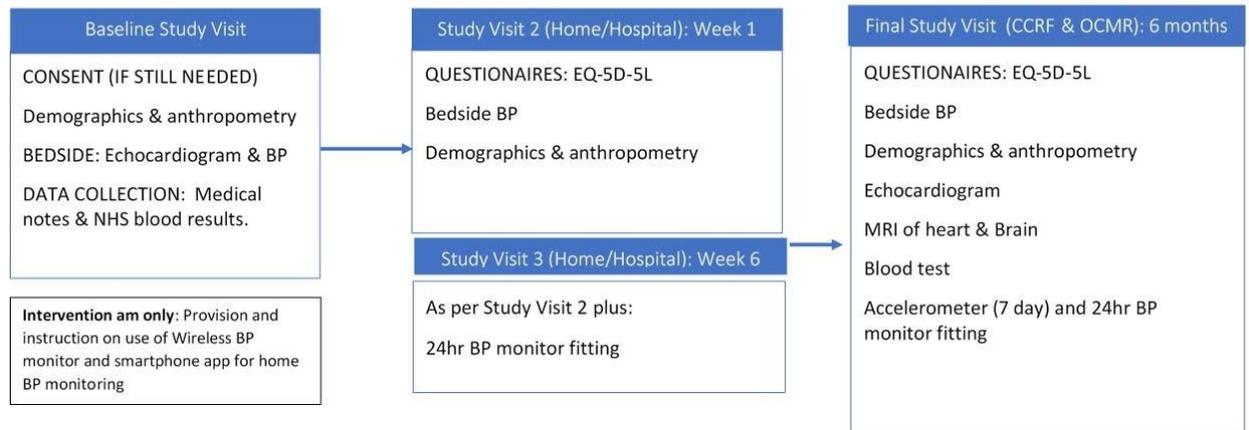

536 **Blinding and code-breaking**

537 Due to the nature of the intervention, participants cannot be blinded. To reduce potential bias in the
 538 investigating team, the study team members performing the baseline and subsequent visits were planned to be
 539 blinded to the randomisation and this took place prior to the COVID-19 pandemic with randomisation and
 540 allocation occurring as outlined in the above section. However, as a result of COVID-19 there was a change in
 541 the OUH trust visitor policy and this prompted a change to the randomisation process, as detailed above, so it
 542 became impossible to maintain blinding. The study thus became a PROBE trial. However to maintain the trial's
 543 fidelity, as per discussion in the TSC/DMEC the outcome data will be analysed by members of the study team
 544 blinded to randomisation with results being verified by a second research team member.

545

546 **Assessments**

547 A flow chart of the proposed study visits is seen on the page below (figure 2) with subsequent explanation of
 548 each of the components in each visits in the text that follows. During the baseline visit, the blinded members of
 549 the research team will perform all procedures for participants in both arms i.e. the intervention and the control

All aspects of each visit contained in the boxes above are 'essential' to the study but a number of other 'desirable' procedures will be offered where possible:

1. Lifestyle & diet questionnaire at baseline & 6 months (can be completed at a later date in participants own time)
2. Vicorder® assessment of aortic BP and aortic distensibility/compliance at baseline & 6 months
3. Retinal Imaging at 6 month visit
4. CPET with a focused exercise echo at 40% of maximal predicted workload (mild exertion on a static bike) at 6 month visit
5. Formal review of medical and obstetric history at the final 6 month visit

550 arm. The provision of the study intervention is for the intervention arm only. However, a blood pressure
 551 monitor will be provided to the control arm during the COVID-19 pandemic, as explained in more below.

As the diagram above illustrates, there will be ‘essential’ components in each study visit but as the study team is aware they will be doing the research on women with new-born babies, so some components have been classed as ‘desirable’ to allow for shortening of the study visits if required in some cases, in line with feedback from our PPI sessions. Although we would like all procedures performed in all cases in an ideal world, some of the secondary outcomes are exploratory and will be used to plan larger validation studies in future; hence the reason they are classed as ‘desirable’. Each of the assessments can be interrupted and restarted as needed in a flexible manner should the need to attend the baby/babies arise during the visit.

During the COVID-19 pandemic, the baseline visit was adjusted (as described in Appendix F). This was implemented to reduce the length of time of direct patient contact to just the echo, and to make the Vicorder® test optional. All contact will be done in appropriate PPE for which Dr Kitt is a trainer as well as being well practiced from clinical work during the pandemic.

Baseline visit (week 0):

Demographics and anthropometry:

Assessment will include recording of the antenatal booking height, weight and BMI (obtained from notes) and the mid-left arm circumference.

Bed-side Blood pressure measurement:

Participants will have their blood pressure checked after 5 minutes’ rest using the automated mode of a validated sphygmomanometer. Three blood pressure readings will be taken at intervals of 1 minute. The first reading will be discarded and not used toward the mean blood pressure calculated for the visit. As previously done in SNAP-HT [4], measurements will be done on the left arm using automated DINAMapV100® blood pressure monitors, ensuring the appropriate cuff size for the arm circumference. The measurement technique advised by the British Heart Foundation and NICE NG133 will be strictly followed i.e. participant will be sat/laying, advised not to talk at the time of measurement and, the arm will be supported and elevated to the height of the heart, with the legs uncrossed.

Echocardiogram (cardiac ultrasound) scan:

Cardiac ultrasound imaging will be performed by a trained sonographer to evaluate cardiac structure and function. Resting transthoracic echocardiography will be performed in the left lateral decubitus position using a commercially available Philips CX50, Philips EPIQ 7C, Philips IE33 or equivalent cardiology ultrasound machine. British Society of Echocardiography guidelines will be followed for collection of a standard clinical imaging dataset

Collate data from medical notes and review blood results:

This part of the study visit will not require participant involvement/participation. A study team member will review the medical notes (paper and electronic) to document the following information: Gestation at diagnosis, gestation at delivery, the numbers of days of antenatal blood pressure treatment, the mode of delivery, the number and doses of anti-hypertensive drugs used post-natally, whether ACE inhibitors are prescribe or not at the time of enrolment, the baby (babies) weight(s) and, the presence of IUGR (defined as AC<40%). The team will also record the day 1 postnatal blood results, the urine PCR at its peak and the sFLT/PIGF ratio is measured, all medications prescribed at the time of enrolment and, any other medical and obstetric history of note.

Quality of Life questionnaire (EQ-5D-5L):

Participants will be provided with an EQ-5D-5L questionnaire via e-mail and a trained study investigator will run through the structured questionnaire during the visit with the participant. If required, there will be an option to complete the questionnaires later

Desirable: Vicorder® (Vascular Measures and Central Blood Pressures):

Resting measures of vascular stiffness including pulse wave velocity and central blood pressure will be collected using a non-invasive device (Vicorder®).

609 Desirable: Lifestyle and diet questionnaire:
610 Study visit participants will be asked to complete a study questionnaire. The questionnaire combines validated
611 questions piloted or used in previous studies. Information will be collected on factors that affect blood pressure
612 including: smoking frequency, alcohol and salt intake, exercise and family history. This is being done via e-
613 mail to avoid all paper use during COVID-19, and participants can complete this at a later date in their own
614 time.

615
616 Desirable: Blood test (10 minutes):
617 A venous blood sample (approximately 25mls) will be taken at rest and include samples for analysis of
618 biomarkers associated with inflammation, angiogenesis and endothelial activation as well as endothelial colony
619 forming cells (ECFCs) in 20/200 participants who enter the endothelial cell sub-study. Blood tests will be
620 taken, where possible, at the same time as clinically indicated venepuncture.

621
622 Intervention provision: Automated blood pressure cuff provided and POP-HT app installed (those randomised
623 to intervention arm only):
624 At the end of the baseline visit, those individuals that randomised to the intervention arm will be issued an
625 automated blood pressure cuff (OMRON EVOLV®), validated in pregnancy [30]. They will also download the
626 POP-HT smart-phone app and be taught how to use the cuff and app. The participant will then have the
627 remainder of their stay in hospital to practice and will be contacted remotely via tablet if there are any
628 problems. This is to ensure all parties are confident and competent prior to discharge home at which point the
629 intervention will start. A telephone number (9-5pm Monday-Friday) and e-mail address will be provided for
630 any technical problems.

631
632 Control arm during COVID-19:
633 During the COVID-19 pandemic, section 3.1.5 of the RCOG Guidance for maternal medicine in the evolving
634 coronavirus (COVID-19) pandemic, published in July 2020 recommends 'self-monitoring 2-3 times in the first
635 week after discharge for women who have had a hypertensive pregnancy. Therefore, those women allocated to
636 the control arm, who are unable to obtain a monitor from the Oxford Women's centre/NHS service, will be
637 provided with a validated BP home-monitoring device by the trial team to ensure they can adhere to this RCOG
638 guidance during week 1. These monitors will be provided to enable the control arm participants to monitor
639 their own blood pressure and in turn liaise with their own GP/midwife to adjust their management based on
640 their readings. The study team will not be offering remote management to the control arm or providing them
641 with an app, or interpretation of the readings and management decisions are to be taken by their own
642 GPs/clinicians. These monitors will also be used to allow remote BP measurements during the study 'visits' at
643 week 1 and 6. They will be returned via the post to the POP-HT team after the 6 weeks visit and duly sterilised.

644 645 **Subsequent visits**

646 During Visits 2 and 3, the research team will perform all procedures for participants in both arms.

647 648 Visits 2 and 3:

649 At visits 2 and 3 at weeks 1 and week 6 (+/- 5 days) post-discharge there will measure blood pressure three
650 times as per the baseline visits, update the demographics and anthropometry, and complete an ED-5D-5L
651 questionnaire. At the end of visit 3, the team will also fit a 24hr blood pressure monitor. These two visits will
652 take place at weeks 1 and 6 post-discharge respectively. They will be offered as a visit to our research facility
653 (CCRF) or a home visit to minimise the trial burden at this busy period in these women's lives. During all
654 home visits, a female chaperone will be made available. We will allow a 5-day window of flexibility for the
655 week 6 visit but cannot allow any longer than 5 days as it may affect the validity of the data. In extenuating
656 circumstances such as COVID-19 all aspects of Visits 2 and 3 will be conducted remotely via video (and/or
657 phone call).

658 659 Demographic and anthropometry:

660 Height, weight, mid-left arm and waist and hip circumference will be performed by the research team for those
661 visits done in person. If done remotely, weight will be obtained using a set of home scales and midleft arm
662 circumference will be measured from the left arm at rest. The measurement will be done by the
663 participant/family member under direct video supervision/guidance to ensure consistency. Waist and hip will
664 not be recorded for remote visits at week 6.

665
666 Blood pressure measurement:
667 Assessment will be performed as outline above for baseline visit. During COVID-19 the readings will be done
668 under direct video supervision using the same BHF gold-standard approach described above. 3 blood pressure
669 measurements will be obtained at 1-minute intervals. The values will be shown on screen and then recorded by
670 the study team.

671
672 Quality of Life questionnaire (EQ-5D-5L):
673 Participants will be provided with an EQ-5D-5L questionnaire via e-mail and a trained study investigator will
674 run through the structured questionnaire during the visit with the participant. If required, there will be an option
675 to complete the questionnaires later.

676
677
678 Visit 3 only: 24hr ambulatory blood pressure monitor (to be worn for 24-hour period)
679 24-hour ambulatory blood pressure monitoring will be initiated at the end of the study visit using validated,
680 calibrated, automated oscillometric, ambulatory devices (SPACELABS® 90217 or equivalent). Correct cuff
681 size will be chosen based on arm circumference recorded at week 1 and 6. Subjects will be instructed to
682 remain still during measurements. Measurements will be automatically taken every 30 minutes during
683 daytime and then hourly nocturnally from 22:00 PM to 7:00AM. Subjects will complete a diary documenting
684 hours asleep and awake and any exertion that could inflate a reading artificially. A member of the study
685 team will fit the ambulatory blood pressure monitor for those visits done 'in person' but, during COVID-19
686 the 24hr cuff, diary and monitor will be posted to participants and the fitting will be performed via video call
687 by trained, experienced study investigators. An adequate cuff fit will be checked by performing one manual
688 reading, which is then excluded from data analysis. The participants will then be asked to post the equipment
689 back to CCRF in a pre-paid, pre-addressed envelope where adequate sterilisation and quarantine of the
690 equipment will be performed prior to data upload. ABP data will be verified by a trained study investigator.

691
692 Visit 4 (6 months (up to 12 months) post-partum)
693 Participants will be invited to a final study visit at CCRF and/or OCMR. This is the longest and most
694 comprehensive visit but once again, there are essential and desirable components, which means the visit, can be
695 shortened if required. A female chaperone will be offered if desired and where possible all echocardiography
696 will be performed by a female sonographer. In extenuating circumstances, such as COVID-19 national
697 lockdowns, where participants do not wish to attend in person, or where our facilities is redeployed as a
698 COVID escalation areas; the 24hr BP monitoring and the procedures below can be conducted remotely via
699 video call. Otherwise, these will be performed in person as described for the baseline visit.

700
701 Demographics and anthropometry:
702 Assessment will be performed as outlined above

703
704 Blood pressure measurement:
705 Assessment will be performed as outlined above

706
707 Quality of Life questionnaire (EQ-5D-5L):
708 This will be e-mailed to the participant as outlined above.

709
710 Fitting of a home blood pressure monitor:
711 Assessment will be performed as outlined above for visit 3

712
713 Fitting of an activity monitor:
714 For remote video calls, the accelerometer will be pre-programmed based on participant reported height, weight
715 and hand dominance and then posted to the participant and they will be shown how to fit it via video call. This
716 consists of an activity monitor placed inside a rubber wristband. It is shock and waterproof so participants can
717 shower/swim with it on. Wrist-worn accelerometers have high compliance and reliability and are validated
718 measures of physical activity. Participants will be asked to wear the accelerometer for 7 days, 24 hours per day
719 and a 7 day interval will be pre-programmed to allow for postage. A stamped addressed envelope will be
720 provided to return the device after use. Participants will be asked to perform whatever activities they would

721 normally do, whilst wearing the accelerometer, to try and accurately reflect their normal levels of daily activity.
722 For visits done as normal, the accelerometer will be programmed during the visit, based on their height and
723 weight recorded as part of the study visit and, fitted to their non-dominant wrist.

724

725 Review of medical and obstetric history and any medication side effects:

726 The study investigator will record any side effects to current/previous medication including blood pressure
727 medication as well as record any medical problems they have developed since discharge from hospital.

728 This information will be obtained from the participant and corroborated with the medical notes as required. If
729 the participant does not want to be involved in this aspect due to time constraints, the medical notes alone will
730 be used to obtain this information. In cases where the above measures are performed remotely the following
731 procedures, which cannot be done at remotely will be scheduled as soon as possible after, and within the
732 12month time window defined in this protocol, when the participant feels safe to come to a hospital site again.
733 For all other participants, all procedures will be done during a single study visit.

734

735 Echocardiogram cardiac ultrasound scan:

736 Assessment will be performed as outlined above for baseline visit.

737

738 Vicorder® (Vascular Measures and Central Blood Pressure):

739 Assessment will be performed as outlined above for the baseline visit. The procedure itself will be done during
740 the MRI scan in order that the central/aortic pressure obtained by the Vicorder can be correlated with the aortic
741 MRI cine images we acquire.

742

743 Retinal imaging:

744 Retinal photography of the right eye (3 single shot images centred on the optic disc) will be completed using a
745 digital camera and imaging software following an established protocol. Imaging is non-invasive with no
746 requirement for topical drops and does not require removal of contact lenses. These images are deidentified
747 (known only by the study ID) and will be stored on our secure high compliance server for up to 10 years.

748

749 MRI:

750 A 3Tesla (3T) Siemens PRISMA scanner will be used to quantify brain structure and volume, followed by
751 cardiac structure and function, cardiac mapping, measurement of aortic distensibility; and T1 maps of the
752 kidneys.

753

754 Gadolinium contrast (optional):

755 Gadolinium will be offered as an additional optional component to the MRI to those women who are not breast
756 feeding, as part of exploratory work that may feed into a larger future trial. A call will be made to clarify this 2-
757 3 weeks prior to this visit and the additional PIS explains the Gadolinium procedure and risks/benefits in more
758 detail (as detailed in section 17.4). Separate informed consent will be obtained for those women who wish to
759 participate in this aspect of the study prior to the MRI being performed. Before any gadolinium is administered,
760 the last creatinine value taken prior to discharge post-partum (up to 9 months prior) will be reviewed and if
761 normal, a repeat will not be needed. If not available or if elevated from that time or clinical judgement deems it
762 necessary, a repeat finger prick creatinine will be done. If the reading demonstrates an eGFR<60mls/min, the
763 scan will not take place and the procedure for incidental abnormal clinical findings will be followed.

764

765 Blood:

766 A venous blood sample (approximately 25mls) will be taken at rest and include samples for a) whole blood,
767 plasma and serum lipid and inflammatory marker analysis and b) analysis of biochemistry and metabolism and,
768 if women consent to late gadolinium imaging as part of their Cardiac MRI scan, the blood sample will be
769 obtained during cannula insertion in OCMR and an additional vial of blood will be collected to measure serum
770 haematocrit.

771

772 Cardiopulmonary Exercise Testing with exercise echo (30 minutes): Desirable

773 Cardiac function and oxygen requirements in response to an incremental increase in workload will be measured
774 via a cardiopulmonary exercise test (CPET). The exercise protocol is a validated incremental protocol with
775 established use in clinical and research practice. The exercise protocol is currently utilised in ongoing ethically
776 approved studies conducted by the Division of Cardiovascular Medicine, and is performed on a stationary bike.

777 The test commences with resting measures of spirometry. Participants will then exercise with an incrementally
778 increasing workload (increasing resistance to pedal against) up to 4060% of their estimated peak exercise
779 capacity. During the test, heart rate will be recorded using ECG monitoring, blood pressure will be measured at
780 intervals and participants will report effort using the Borg exertion scale and the oxygen consumption and CO₂
781 production will be measured using a calibrated mask. It is a non-invasive, painless technique with no
782 associated risks. An additional brief (2-3 minute) focused echo will be performed at 40% of their maximal
783 predicted exercise intensity (whilst on the bike) to enable measurement of exercise ejection fraction. A female
784 sonographer will be provided wherever possible.

785
786 Follow-up of participant medical records:

787 Participants will be asked to consent to be followed- for up to 10 years. The research team in Oxford will ask
788 for information from NHS Digital. They will send the participants' name, date of birth, NHS number and
789 postcode to NHS Digital (or other central NHS bodies) who can link this information to centrally held records.
790 The team may also want to assess the blood pressure of the participants again in the future (up to
791 10 years from enrolment) as part of a further study visit but this will be submitted as an amendment/extension
792 to this study prior to the study terminating. Participants are not compelled to take part in any extension study
793 by participating in this initial part of this study.

794
795 **Sub- study visits: circulating biomarker validation and evaluation**

796 An additional cohort of participants (n=20 normotensive participants) will be invited to the blood validation
797 and evaluation study only. 20/200 of the hypertensive pregnancy patients from the main trial will also have a
798 blood test taken at baseline as part of their main study visit, for which additional written, informed consent will
799 be sought. For the normotensive participants, the following study procedures and visits listed below remain
800 separate to the main study. Study procedures will be the same during both visits.

801 The baseline visit will be carried out on the postnatal ward, in the Women's Centre, prior to discharge.
802 Normotensive participants will be invited back for a 2nd visit in CCRF/OCMR in the John Radcliffe Hospital
803 between 6-12 months post-partum, and for those 20/200 in the main trial, the repeat blood test for the sub-study
804 will be performed during the main V4/final visit when they have the other routine blood test performed.

805
806 Procedures for all sub-study patients are:

807 Baseline:

808 Demographics and anthropometry (10 minutes):

809 Assessment will include height (obtained from notes), measuring post-natal weight and BMI. Demographic
810 details will be recorded and cross-referenced to the notes.

811

812 Bed-side Blood pressure measurement (10 minutes):

813 Participants will have their blood pressure checked after 5 minutes' rest using the automated mode of a
814 validated sphygmomanometer. Three blood pressure readings will be taken at intervals of 1 minute. The first
815 reading will be discarded and not used toward the mean blood pressure calculated for the visit. The
816 measurements will be done on the left arm using automated DINAMapV100® blood pressure monitors. The
817 measurement technique advised by the British Heart Foundation will be strictly followed as in the original
818 study i.e. participant will be sat, advised not to talk at the time of measurement and, the arm will be supported
819 and elevated to the height of the heart with the legs uncrossed.

820

821 Blood test (10 minutes):

822 A venous blood sample (approximately 25mls) will be taken at rest and include samples for analysis of
823 biomarkers associated with inflammation, angiogenesis and endothelial activation as well as endothelial colony
824 forming cells (ECFCs) Blood tests will be taken, where possible, at the same time as clinically indicated
825 venepuncture.

826

827 Visit 2:

828 Participants will be invited back, between 6-12 months postnatally. Study procedures will be as per listed at
829 baseline. This study visit will take place in CCRF.

830

831 **Sample handling for trial purposes**

832 Blood samples will be centrifuged and the whole blood plasma and serum will be separated and stored. All
833 samples will be retained in a secure environment for future analysis and will be stored in a de-identified format
834 at the University of Oxford under the custodianship of the Division of Cardiovascular Medicine. The samples
835 will be stored for at least 10 years and may be used in future ethically approved studies as our understanding of
836 blood vessel function grows. A copy of the consent will be retained from participants who consented for their
837 samples to be used in future research. All other human materials will be disposed of at the end of the study in
838 accordance with the Human Tissue Authority Code of Practice.

839

840 **Early Discontinuation/Withdrawal of Participants**

841 During the course of the trial, a participant may choose to withdraw early from the trial treatment at any time.
842 This may happen for a number of reasons, including but not limited to:

- 843 • The occurrence of what the participant perceives as an intolerable AE (if this is the reason the
844 participant must undergo an end of trial assessment and be given appropriate care under medical
845 supervision until symptoms cease, or the condition becomes stable)
- 846 • Inability to comply with trial procedures
- 847 • Participant decision

848

849 Participants may choose to stop treatment and/or study assessments but may remain on study follow-up.
850 Participants may also withdraw their consent, meaning that they wish to withdraw from the study completely.
851 Participants may have the following two options for withdrawal and these will be explained to them should the
852 situation arise:

- 853 • Participants can withdraw from the study but permit data and samples obtained up until the point of
854 withdrawal to be retained for use in the study analysis. No further data or samples would be collected
855 after withdrawal.
- 856 • Participants can withdraw completely from the study and withdraw the data and samples collected up
857 until the point of withdrawal. The data and samples already collected would not be used in the final
858 study analysis except where analysis of their data or samples has already been integrated into interim
859 results and this will be explained in the participant information sheet.

860

861 Data collected from participants who wish to withdraw consent from the study will be included in the analyses
862 up to the point of withdrawal of consent unless explicitly stated by the participant that this is against their wish.
863 The participant will not contribute further data to the study and the CI will be informed. Participants do not
864 need to provide any reason for withdrawal; should they freely offer a reason it will be recorded in the CRF.

865 The research team may recruit additional participants to replace participants who have withdrawn.

866 In addition, the Investigator may discontinue a participant from the trial treatment at any time if the

867 Investigator considers it necessary for any reason including, but not limited to:

- 868 • Pregnancy
- 869 • Ineligibility (either arising during the trial or retrospectively having been overlooked at screening)
- 870 • Significant protocol deviation
- 871 • Significant non-compliance with treatment regimen or trial requirements
- 872 • An adverse event which requires discontinuation of the trial or results in inability to continue to
873 comply with trial procedures

874

875 If the participant is withdrawn due to an adverse event, the Investigator will arrange for follow-up visits or
876 telephone calls until the adverse event has resolved or stabilised. If a participant is withdrawn from treatment
877 due to a further pregnancy the pregnancy will be followed-up to outcome. See the Safety Reporting section
878 below.

879

880 **Definition of end of trial**

881 The end of trial is when the 10-year follow-up has been completed or when the last sample has been analysed,
882 whichever is later.

883

10. Study intervention

See accompanying document

11. Safety reporting

Adverse Event Definitions

Serious Adverse Event (SAE)	<p>A serious adverse event is any untoward medical occurrence that:</p> <ul style="list-style-type: none">• Results in death• Is life-threatening• Requires inpatient hospitalisation or prolongation of existing hospitalisation• Results in persistent or significant disability/incapacity• Consists of a congenital anomaly or birth defect. <p>Other 'important medical events' may also be considered a serious adverse event when, based upon appropriate medical judgement, the event may jeopardise the participant and may require medical or surgical intervention to prevent one of the outcomes listed above. NOTE the term "life-threatening" in the definition of "serious" refers to an event in which the participant was at risk of death at the time of the event; it does not refer to an event, which hypothetically might have caused death if it were more severe.</p>
-----------------------------	---

890 Note: to avoid confusion or misunderstanding of the difference between the terms “serious” and “severe”, the
891 following note of clarification is provided: “Severe” is often used to describe intensity of a specific event,
892 which may be of relatively minor medical significance. “Seriousness” is the regulatory definition supplied
893 above.

894

895

Procedures for Reporting Adverse Events

896

A serious adverse event (SAE) occurring to a participant should be reported to the REC that gave a favourable opinion of the study where in the opinion of the Chief Investigator the event was ‘related’ (resulted from administration of any of the research procedures) and ‘unexpected’ in relation to those procedures. Reports of related and unexpected SAEs should be submitted within 15 working days of the Chief Investigator becoming aware of the event, using the HRA report of serious adverse event form (see HRA website).

897

898

899

900

901

The severity of events will be assessed on the following scale: 1 = mild, 2 = moderate, 3 = severe.

902

903

904

Non-serious AEs considered related to the trial intervention as judged by a medically qualified investigator or the Sponsor will be followed up once the event is considered stable. It will be left to the Investigator’s clinical judgment to decide whether or not an AE is of sufficient severity to require the participant’s removal from the trial. A participant may also voluntarily withdraw from the trial due to what he or she perceives as an intolerable AE. If either of these occurs, the participant must undergo an end of trial assessment and be given appropriate care under medical supervision until symptoms cease, or the condition becomes stable.

905

906

907

908

909

910

Events exempt from immediate reporting as SAEs

911

There are a number of expected admissions/consultations with healthcare providers that will be expected take place as part of the natural history of pre-eclampsia and gestational hypertension during the trial period. These will be classed as ‘Foreseeable Events’ exempt from reporting as SAEs and include:

912

913

914

915

- Severe hypertension;
- Maternal morbidity: TIA; blindness; inotropic support; pulmonary oedema; respiratory failure; SpO2 <90%; myocardial ischaemia or infarction; hepatic dysfunction, hepatic haematoma or rupture; acute kidney injury; or transfusion;
- Post-partum haemorrhage;
- Lower genital tract bleeding;
- Sepsis;
- Admission to hospital for pre-eclampsia, monitoring of hypertension, or symptoms of low blood pressure

916

917

918

919

920

921

922

923

- 924 • Pre-planned hospitalisation;
- 925 • Diagnostic and therapeutic procedures;
- 926 • Worsening pruritis;
- 927 • A pre-existing maternal condition (such as renal disease), unless it causes increased clinical
- 928 concern;
- 929 • Admission for psychiatric or social reasons;
- 930 • Retained placenta;
- 931 • Extended hospital stay of the mother due to the need to keep her baby in hospital;
- 932 • Neonatal care unit admission for indications unrelated to pregnancy hypertension, such as neonatal
- 933 hyperbilirubinaemia or unanticipated care for a fetal anomaly; or
- 934 • Fetal congenital anomaly

935
 936 This list is not exhaustive and therefore any other ‘minor medical significance symptom’ as judged by the
 937 CI/PI, which does not require inpatient hospitalisation or prolongation of existing hospitalisation or result in
 938 persistent or significant disability/incapacity, is not life-threatening and, does not result in death will not be
 939 classed as an adverse event not an SAE.

940
 941
 942 **12. Statistics**

943 **Statistical Analysis Plan (SAP)**

944 The statistical aspects of the study are summarised here with details fully described in a statistical analysis plan
 945 included in a separate section of this supplementary material.

946
 947 **Description of Statistical Methods**

948 The analysis will be carried out on the basis of intention-to-treat (ITT). This is, after randomisation,
 949 participants will be analysed according to their allocated intervention group irrespective of what treatment they
 950 actually receive. Patient demographic characteristics and other baseline information will be summarised by
 951 treatment group. Numbers (with percentages) for binary and categorical variables and mean (standard
 952 deviation), or median (interquartile or full range) for continuous variables will be presented. The analysis of the
 953 primary outcome will be assessed using a mixed effects model with baseline value, minimisation factors used
 954 in the randomisation process, randomised group and time will be fitted as fixed effects with a random intercept
 955 for each participant. Results will be presented as adjusted mean difference in change in mean ambulatory
 956 diastolic blood pressure between randomised groups at 6 months with 95% confidence intervals (CI) and
 957 associated two-sided p value. Secondary blood pressure outcomes will be analysed using the same method.
 958 Other secondary outcomes will be analysed using analysis of covariance (ANCOVA) to establish a co-variant
 959 model to examine the effect of blood pressure control in the postpartum period on cardiac structure and
 960 function, vascular function and cerebro-vascular structure and function. If the model assumptions are not met
 961 and evidence of departure from normality is observed, transformations of the data will be employed or non-
 962 parametric tests will be carried out.

963
 964 Descriptive statistics (mean, standard deviation, standard error, range, etc.) will also be calculated for each
 965 outcome for each group. Differences in the primary and secondary outcomes will be compared between
 966 intervention and control groups.

967
 968 Mean changes in blood pressures will be compared across the population and correlated with cardiovascular
 969 endpoints including cardiac structure and function reported from cardiac MRI and echocardiogram.
 970 Demographic and physiological characteristics of the participants will be added to regression models as
 971 covariates to explore the determinants of change in blood pressure comparing intervention and control groups.

972
 973 **Sample size determination**

974 Power calculations to determine adequate sample sizes for this trial are summarised below:
 975 Primary outcome measure: 24-hour average diastolic blood pressure (mmHg) at 6-9 months post-partum as
 976 assessed by SPACELAB 90217 24hr Ambulatory blood pressure monitor

Sample size calculation: The detection of BP differences between the 2 arms of this trial is based on the mean diastolic blood pressure difference detected in the pilot SNAP-HT study at 6 months. The mean BP difference detected between the intervention and control arm at the 6 month time-point was -4.5mmHg. We have used a more conservative standard deviation (SD) of 10mmHg in each arm (in SNAP-HT the SD was 8.2mmHg in the intervention arm and 9.8 mmHg in the standard care arm) and 10mmHg SD is in keeping with pooled SDs for ambulatory diastolic blood pressure readings from other studies. To detect a treatment effect on diastolic blood pressure of -4.5mmHg, powered to 80% at $p=0.05$ requires a total sample size of 158 and with 1:1 randomisation this would require 79 in each arm. We have adjusted our power calculations to determine the final sample size, to allow for up to 20% loss to follow up/withdrawal based on prior experience. Thus, we aim to recruit 100 to the intervention and 100 to the control arm.

Secondary outcome hypothesis: Improved blood pressure control in the post-partum period (0-9 months) in POP-HT will result in improved cardiac, vascular and cerebrovascular phenotypes at 6-12 months postpartum

Secondary outcome power calculations:

- Cardiac structure: Studies using echocardiography by our collaborators have compared BP and LV mass in pre-eclampsia patients and control patients, at 1-year post-partum [19, 31][19, 31][19, 31][19, 31][19, 31][19, 31]. They found that a difference in BP at 1 year of 10mmHg in diastolic BP corresponded to significant differences in LV mass. SNAP-HT appeared to achieve a 50% reduction of anticipated BP difference seen between pre-eclamptic and normotensives at 1 year by 6 months i.e. ~5mmHg. If it is assumed that the structural/phenotypic benefit results from the BP benefit, as we are hypothesising, then we must power to detect 50% of the phenotypic difference.

In previous work by our group it has been demonstrated significant differences in LV mass/EDV (g/ml) in a similar age and predominantly female population with similar mean diastolic BP differences between groups to that seen in SNAP-HT. The LV mass/EDV (g/ml) in the group with high normal blood pressure was 1.54g/ml vs. 1.22 g/ml in those with optimal blood pressure with a standard deviation of 0.33 and 0.27 respectively at $P<0.001$. Based on these assumptions, to observe a treatment effect of 0.16 (50% of the difference between 1.54g/ml and 1.22g/ml) on LV mass/EDV, requires 67 in the intervention arm and 67 in the control arm (132 total). This is calculated using the larger SD of 0.33 referenced above at a power of $>80%$ to detect a difference between the groups at $p=0.05$. This number should take into account for the greater dropout rate we may see for the MRI outcomes.

- Brain White matter integrity: Work by our group, on pre-eclamptic pregnancy, showed an increased burden of temporal lobe white matter lesion volume 5-10 years after a pre-eclamptic pregnancy ($23.2 \pm 13 \mu\text{l}$) vs matched individuals who had a normotensive pregnancy ($10.9 \pm 11.5 \mu\text{l}$) at $p<0.05$. If we again assume we can detect a 50% of the phenotypic benefit with our intervention as outlined above, we would anticipate a 50% reduction in the burden of white matter lesions i.e. $6.15 \mu\text{l}$ (50% of $23.2 - 10.9 \mu\text{l}$) in the intervention arm. With 71 in the intervention group and 71 in the control group (142 total), this will provide $>80%$ power at $p=0.05$, even using the more conservative SD of 13ul to detect a 50% improvement in white matter lesion volume between the intervention and the control group. This number should take into account for the greater dropout rate we may see for the MRI outcomes.

- Aortic compliance: Several studies assessing the impact of blood pressure on aortic compliance have shown that even modest reductions in systolic/diastolic blood pressure increase aortic distensibility/compliance. One such study had a mean difference in systolic blood pressure of 4.6mmHg between the 2 drug treatment arms at 52 weeks, akin to the same mean difference in SNAP-HT at 6 months, albeit this was diastolic not systolic, although other studies have suggested diastolic BP may be even more important in influencing aortic compliance. In this study with a mean 4.6mmHg difference in systolic BP there was a treatment difference of 0.12 [(95% CI -0.35, 0.60), $P=0.60$ in aortic compliance. Based on these assumptions, to observe a treatment effect from our intervention, with 100 in the intervention and 100 in the control arm we will be more than powered at $>90%$ to detect a difference at $P=0.05$ in POP-HT.

- 1033 • Exercise ejection fraction: Huckstep et al from our group compared resting and exercise ejection
1034 fractions for young adults with high normal BP vs. a normotensive cohort. The cohort was very well
1035 matched demographically to our planned study cohort, albeit it included both males and females.
1036 Resting ejection fraction (by Biplane Simpson's) was similar between groups but at 40%60% of peak
1037 exercise intensity, the higher blood pressure group had a lower exercise ejection fraction than the
1038 normotensive cohort (73.9±3.25 vs. 80.0±4.54%, p<0.001) and in keeping with this, a smaller increase
1039 in ejection fraction when going from baseline to 40% exercise intensity (10.4±5.92 vs. 19.0±6.90%,
1040 p<0.001). Assuming the ~5mmHg mean BP improvement achieved in SNAP-HT again translates to a
1041 50% phenotypic benefit, when assessing exercise ejection fraction we anticipate a 4.3% improvement
1042 in exercise stress ejection fraction in the intervention arm vs. the control arm (4.3% is 50% of the
1043 difference i.e. 50% of 10.4-19%). With 43 participants in the intervention arm and 43 in the control
1044 arm (86 total) we will be powered at >80% to detect such a difference.

1045 .

1046 **Analysis populations**

1047 The participants that will be included in the analysis will be all of those randomised. All data will be included
1048 in the analysis as far as possible to allow full ITT analysis, though there will inevitably be the problem of
1049 missing data due to withdrawal, loss to follow-up or non-completion of questionnaire data.

1050

1051 **Decision points**

1052 There will be no formal interim analysis. The results once analysed will be reviewed by the research team, the
1053 Trial Steering Committee (TSC) and Data and Safety Monitoring Committee (DSMC) and the PI/CI and other
1054 collaborators.

1055

1056 **The level of statistical significance**

1057 Level of significance will be tested as a 5% two-sided significant level.

1058

1059 **Procedure for accounting for missing, unused, and spurious data**

1060 Missing data: Missing data will be reported with reasons given where available and the missing data pattern
1061 will be examined. We will explore the mechanism of missing data, though the mixed effects model implicitly
1062 accounts for data missing at random. The need for a sensitivity analysis taking into account missing data using
1063 multiple imputation will be considered. Spurious data will be assessed using standard editing criteria.

1064

1065 **Procedures for reporting any deviation(s) from the original statistical plan**

1066 The final statistical plan will be agreed prior to final data lock and prior to any analyses taking place. Any
1067 deviation thereafter will be reported in the final trial report.

1068

1069

1070 **13. Data management**

1071 The data management aspects of the study are summarised here with further details fully described in the Data
1072 Management Plan.

1073

1074 **Source data**

1075 Source documents are where data are first recorded, and from which participants' CRF data are obtained. These
1076 include, but are not limited to, paper and electronic hospital records (from which medical history and previous
1077 and concurrent medication may be summarised into the CRF), clinical charts and laboratory and pharmacy
1078 records. CRF entries will be considered source data if the CRF is the site of the original recording (e.g. there is
1079 no other written or electronic record of data). All documents will be stored safely in confidential conditions.
1080 On all trial-specific documents, other than the signed consent, the participant will be referred to by the trial
1081 participant number/code, not by name.

1082

1083 **Access to Data**

1084 Direct access will be granted to authorised representatives from the Sponsor, host institution and the regulatory
1085 authorities to permit trial-related monitoring, audits and inspections.

1086

1087 **Data Recording and Record Keeping**

1088 The study will comply with the General Data Protection Regulation (GDPR) and Data Protection Act 2018.
1089 The University of Oxford, as sponsor will act as data controller for the study.

1090
1091 Electronic documents that contain participants' personal identifying information such as the code-break
1092 document will be stored on the secure University of Oxford High Compliance system, a service for Clinical
1093 Trials Units (CTUs) and Medical Division Departments that securely accesses applications and stores sensitive
1094 data. This remote data capture system is fully compliant with ICH-GCP requirements. Personal data on paper
1095 documents such as informed consent forms will be stored securely in lockable cabinets with restricted access
1096 by authorised personnel only. The Chief/Principal investigator is responsible for keeping these documents
1097 encrypted where possible and to make sure that such documents are kept securely to ensure that in case of an
1098 emergency, participants can be identified and contacted. All source documents will have all identifiers
1099 removed and replaced by only the study ID number as soon as possible.

1100
1101 Study data will be recorded in a pseudo-anonymised manner and processed electronically where applicable and
1102 participants would not be identifiable from this. All participants will be identified by a code number (Study ID
1103 number) on case report forms and any electronic databases i.e. they will be de-identified. During the study, the
1104 hard copy data will be stored securely and at the end of the study, this will be archived in a secure archive
1105 location with restricted access.

1106
1107 Personal data (such as contact details and information that could identify a participant, except from those who
1108 have consented for future approach) will be destroyed as soon as it is practical to do so and no later than 12
1109 months after the end of the study. Retinal images will be de-identified (known only by the study ID) and will
1110 be stored on our secure high compliance server for up to 10 years. The personal identifiers (name of
1111 participant) contained in consent forms and the code break document will be stored or accessed for up to 10
1112 years after study end, after which time the custodian will agree a date for destruction and it will be destroyed
1113 confidentially.

1114
1115 Electronic data will be held on secure network drives/hard disks/servers on password-protected computers.
1116 Backup copies of files will be made regularly and stored on a different secure server/external hard drive. These
1117 back up locations will be subject to the same security principles as the primary locations. When datasets are
1118 complete, the primary copy will remain at the study site where it will be transferred onto optical media, e.g.
1119 DVD/external drives and undergoes archiving for hard copy data. Any copies leaving the study site will be de-
1120 identified.

1121
1122 All de-identified study data will in turn be entered onto a password protected, electronic cloud based software
1123 kept in England, called 'Castor EDC'. Castor EDC is an electronic data capture and management system that
1124 permits secure multi-site access. The server is based in the UK and it complies with relevant laws to ensure that
1125 the data is held securely. The participants will be identified by a unique study specific participant ID in this
1126 database also and will not be identifiable from this.

1127
1128 Information held and maintained by NHS Digital/ Office for National Statistics (ONS) may be used to provide
1129 information about health status and the NHS number, date of birth and postcode may be shared securely to
1130 obtain such information and allow contact for blood pressure, and other relevant measurements over the next
1131 10 years.

1132
1133 The POP-HT software interfaces facing the participants (web-application, mobile app and SMS system) will
1134 display their first and last name and their phone number alongside the clinical data required to manage their
1135 post-partum hypertension through each system. This was shown in PPI meetings for this study and intervention
1136 testing for POP-HT and for BUMP (NCT03334149) to help establish trust with the software (i.e. they confirm
1137 more easily the data related to each of them). All of this information is deleted from the system within 12
1138 months as per the other personal data discussed in the section above.

1139
1140 Researchers, obstetricians and midwives authorised to login into the patient management web-application will
1141 also see this data but will only see initials, study ID and contact numbers, not full names.

1142

1143 Beyond these interfaces, all patient data is associated with either their unique study ID, or with a random
1144 number generated by the system called a UUID. For example, any e-mails generated to the study team will
1145 only use the study ID to identify the participants. On the other hand, the web-application usability data (i.e.
1146 number of page-views, number of clicks, and city-based location information, derived from the IP address used
1147 to access the interface) that is tracked using vendors such as google analytics, will use UUID (the random
1148 number generated on first log-in specific to that participant) to track these data. The mobile app and web-
1149 application data used to manage the patient condition is held on the secure server in the OUHNHS intranet,
1150 only accessible via a secure log-in portal (i.e. the web-application) hosted in a different OUH-NHS server to
1151 that which is open to the internet. All data is communicated using encrypted channels: data communication
1152 from/to the web-application and mobile app will use HTTPS (SSL/TLS encryption protocols); the security of
1153 SMSs sent to the patients is managed by the SMS service company (i.e. Esendex), and the UK-based mobile
1154 operator provider of each patient.

1155
1156 Only those researchers within CCRF directly involved in the study will be provided with a log-in, as well as the
1157 CI/PI, the obstetricians involved in clinical care and the technical support team from OIBME. As participants
1158 will only be identified by initials, study ID and contact number it will not affect the blinding of the research
1159 team as all of these participants are in the intervention arm and it will not be realistically possible to link back
1160 to a particular participant without accessing the high compliance database where such information will be
1161 stored. This would only be done in the event of unblinding being required. If a researcher is accidentally un-
1162 blinded, they will not partake in subsequent downstream data analysis.

1163
1164 Users with administration roles in the web-application are able to export a pseudo-anonymised version of the
1165 trial data (i.e. initials and phone number are removed) through the web-application. All the data stored in the
1166 OUH-NHS intranet server are backed-up daily in the same server. Only data from the last 3 days are kept. The
1167 backups are further encrypted using an AES encryption protocol.

1168
1169

1170 **14. Quality assurance procedures**

1171 **Risk assessment**

1172 The trial will be conducted in accordance with the current approved protocol, GCP, relevant regulations and
1173 standard operating procedures. A risk assessment and monitoring plan are not being prepared before the study
1174 opens, as it is a low risk intervention.

1175

1176 **Monitoring**

1177 Direct access will be granted to authorised representatives from the Sponsor within the appropriate department
1178 and host institution for monitoring and/or audit of the study to ensure compliance with regulations. Following
1179 written standard operating procedures, the monitoring visits will verify that the clinical trial is conducted and
1180 data are generated, documented and reported in compliance with the protocol, GCP and the applicable
1181 regulatory requirements.

1182

1183 **Trial Steering Committee**

1184 A trial steering committee (TSC) will convene prior to the study starting and half-yearly thereafter to review
1185 and address key aspects of the study including the following:

- 1186 • Recruitment
- 1187 • Safety/adverse event
- 1188 • Withdrawals
- 1189 • Data management
- 1190 • Statistical analysis plan

1191 The TSC will also function as a data safety and monitoring committee (DSMC) for this particular study and
1192 there will be a smaller trial management committee as outlined in the study synopsis, which will focus more on
1193 the week-to-week running of the trial and will be on a more regular basis.

1194

1195

1196 **15. Protocol deviations**

1197 A trial related deviation is a departure from the ethically approved trial protocol or other trial document or
1198 process (e.g. consent process) or from Good Clinical Practice (GCP) or any applicable regulatory requirements.
1199 Any deviations from the protocol will be documented in a protocol deviation form and filed in the trial master
1200 file.

1201

1202 A standard operating procedure is in place within CTRG in the University of Oxford for identifying
1203 noncompliances, escalation to the central team and assessment of whether a non-compliance /deviation may be
1204 a potential Serious Breach.

1205

1206

1207 **16. Serious breaches**

1208 The Medicines for Human Use (Clinical Trials) Regulations contain a requirement for the notification of
1209 "serious breaches" to the MHRA within 7 days of the Sponsor becoming aware of the breach. A serious
1210 breach is defined as "A breach of GCP or the trial protocol which is likely to affect to a significant degree:

1211 • The safety or physical or mental integrity of the subjects of the trial; or
1212 • The scientific value of the trial".

1213

1214 In the event that a serious breach is suspected, the Sponsor must be contacted within 1 working day. In
1215 collaboration with the CI, the serious breach will be reviewed by the Sponsor and, if appropriate, the Sponsor
1216 will report it to the REC committee, Regulatory authority and the relevant NHS host organisation within seven
1217 calendar days.

1218

1219

1220 **17. Ethical and regulatory considerations**

1221 **Declaration of Helsinki**

1222 The Investigator will ensure that this trial is conducted in accordance with the principles of the Declaration of
1223 Helsinki.

1224

1225 **Guidelines for Good Clinical Practice**

1226 The Investigator will ensure that this trial is conducted in accordance with relevant regulations and with Good
1227 Clinical Practice.

1228

1229 **Approvals**

1230 Following Sponsor approval, the protocol, informed consent form, participant information sheet, participant
1231 invitation letters and study advertising materials will be submitted to an appropriate Research Ethics
1232 Committee (REC), HRA, and MHRA for written approval. The Investigator will submit and, where necessary,
1233 obtain approval from the above parties for all substantial amendments to the original approved documents.

1234

1235 **Other Ethical Considerations**

1236 Study visits

1237 See Appendix F for the additional considerations required during the COVID-19 pandemic.

1238

1239 The clinical team will contact the research team via 'Whatsapp' ® messaging in which no 'patient identifiers
1240 such as name, date of birth or address' will be mentioned, although this form of communication does have
1241 secure end-to-end encryption e.g. clinical team will send message stating 'eligible patient on MAU in bed 5.
1242 Will provide details when you arrive on ward.'

1243

1244 All of the initial procedures in the baseline visit will be done at the bedside to minimise the burden of study
1245 participation and to allow mum and baby/babies to remain together and feed as and when is needed. The
1246 provision of home visits for week 1 and 6 is also to minimise the burden on the participant.

1247

1248 The final study visit, can take up to a maximum of 4 hours at a busy time in the participants' lives. This has
1249 been considered in several PPI meetings. The consensus of agreement was to minimise the burden on the mum
1250 and child/children. It was thus agreed that the team would contact the participant several weeks prior to the
1251 final visit and:

- 1252 • Participants will be advised to try and make arrangements for the child not to attend the visit e.g.
1253 determine whether plans can be made to stay with the father or other family members.
- 1254 • Where this is not possible, help with child-care can be offered by research midwives with the relevant
1255 DBS approval and safe-guarding training, and places for breast-feeding, a nappy changing area, and a
1256 box of child's entertainment will be provided. A double-bedded bay will be booked for this visit so
1257 there is enough space for feeding and playing.
- 1258 • We can also offer split MRI visits in some cases (as long as the MRI does not extend beyond 9 months
1259 from enrolment).
- 1260 • We have also made a distinction between essential procedures (which must take place) and some of
1261 the more exploratory secondary desirable procedures (which could be skipped if it necessary to
1262 shorten the visit) as per the diagram in section 9.

1263

1264 24 hour Ambulatory Blood Pressure and week-long activity Monitoring

1265 Wearing an ambulatory blood pressure monitor has no risks and causes no pain. It is used routinely in hospital
1266 outpatients to assess blood pressure variation over a 24-hour period. The regular inflation and deflation of the
1267 cuff at regular time points may be initially unsettling to the participant however, it is unlikely that it will disturb
1268 their sleep, particularly as the cuffs provided as comfier than standard NHS monitors, the monitors can be
1269 programmed to be silent, and the frequency of readings is reduced (compared to the NHS) to minimise the
1270 burden. These details are explained in the PIS and participants will be shown how to use the device and
1271 provided with the relevant device information sheet. A trained member of the study team will also show
1272 participants how to re-attach it as it is routinely removed for a bath or shower and, they will be asked to remove
1273 it for any period of intense cardiovascular activity e.g. competitive sport, where the readings would be not
1274 representative of their normal ambulatory blood pressure. They can also remove it for short periods during the
1275 24hr period where it may be an inconvenience. The weeklong activity monitor (accelerometer) is no different
1276 to wearing a wrist-watch and carries no risk and causes no pain.

1277

1278 Unexpected health related findings

1279 It is possible that the study investigations could uncover unexpected disease findings. For any abnormalities
1280 confirmed, the CCRF departmental SOP (approved by University of Oxford) will be followed. A designated
1281 clinical specialist will discuss the implications with the participant and, with the consent of the participant, may
1282 arrange for further investigations as necessary. Participants will be aware from the PIS that research studies are
1283 not for diagnostic purposes, and therefore are not a substitute for a clinical appointment. Investigators will gain
1284 permission from the participant to contact their general practitioner (GP) directly so that the GP can then
1285 arrange appropriate management, or will refer the participant to a specialist hypertension clinic.

1286

1287 Sensitive issues

1288 When addressing the exclusion criteria e.g., 'a significant new co-morbidity that makes enrolment unsafe or
1289 impractical' the study team are aware that this may be a sensitive issue and cause distress. The questions will
1290 thus be phrased as compassionately as possible and team members will be briefed in advance on how to broach
1291 this aspect of the study visit.

1292

1293 Language barriers

1294 Those without acceptable English language skills will be excluded as it would be hard to safely ensure they are
1295 able to comply with self-management as all the instructions, reminders and contact with the research team will
1296 be done in English.

1297

1298 Home visits

1299 In line with the University's lone working policy [[https://www.admin.ox.ac.uk/safety/policy-
1300 statements/s508/#d.en.21010](https://www.admin.ox.ac.uk/safety/policy-statements/s508/#d.en.21010)] whenever visiting participants in their home, researchers will inform a staff
1301 member at research site where they are going to be. The researcher will telephone that person when they arrive

1302 at the home. If the researcher has any concerns about the situation, then he/she will leave immediately. Ideally,
1303 no research will be undertaken in a participant's home unless two people can conduct the visit together,
1304 although it is appreciated that this is not always possible. If there is thought to be a significant risk associated
1305 with a particular visit, a specific risk assessment (expanding on the points above) will be made and recorded.
1306

1307 Appropriate safeguards are in place for 'safe-guarding' which follow the University of Oxford's safeguarding
1308 code of practice. This was devised in response to the Safeguarding act of 2015, 'Working Together to Safeguard
1309 Children 2015'. The full policy is detailed at:

1310 <http://www.admin.ox.ac.uk/personnel/cops/safeguarding/safeguardingcop/>

1311

1312 The University Council approved this policy on 22 June 2015 to take effect from 1 October 2015. In line with
1313 this, all staff working on the study Extension are familiar with the Universities' child protection policy and
1314 procedures for dealing with issues of concern or abuse (full policy outlined in the link above). The study
1315 investigators working on the study have also undertaken the Oxfordshire Safeguarding Children Board's
1316 'introduction to safeguarding' e-learning training, in line with the University's recommendations as part of their
1317 policy. They all have appropriate certification of satisfactory completion of this training and the PI will
1318 delegate any safe guarding matters to a nominated study team member. The nominated safeguarding contact for
1319 the study is responsible for ensuring that concerns and allegations are escalated to the appropriate [University](#)
1320 [Safeguarding Officer](#) immediately as outlined further in this hyperlink
1321 (<http://www.admin.ox.ac.uk/personnel/cops/safeguarding/safecontact/>).

1322

1323 Phlebotomy (and Cannulation for those in the gadolinium sub-study)

1324 Risk to Participants: Common risks associated with phlebotomy and cannulation are pain during the procedure
1325 and bruising (with associated pain afterwards). The worry associated with taking blood may cause some
1326 participants to feel unwell or faint before, during or after the procedure. The risk associated with this will be
1327 reduced by having an adequately equipped facility for performing the procedure and having a staff member
1328 trained in basic life support. Although phlebotomy and cannulation is a very safe procedure, it does create a
1329 puncture wound on the skin, which may very rarely lead to infection around the puncture site. The risk of this
1330 will be minimised by ensuring strict hygiene during the procedure. In the event that a participant reports
1331 symptoms of an infection (local redness, swelling, pain or discharge of pus) they should be referred to their GP
1332 or to A+E urgently.

1333

1334 Risk to Researchers/Other Staff: Taking blood carries a risk of needle stick injury to the phlebotomist, which in
1335 turn carries a risk of exposure to blood borne infections. This risk will be minimised by a) ensuring staff are
1336 adequately trained, b) ensuring staff have been vaccinated against, and show immunity to Hepatitis B and c)
1337 having a local policy for needle stick injury which describes the process of being assessed for and receiving
1338 post exposure prophylaxis.

1339

1340 Echocardiogram cardiac ultrasound scans

1341 Although echocardiography carries no risk of physical harm to the participant, there is a risk to personal
1342 discomfort or embarrassment to the participant. This is minimised by providing gowns or scrubs to maintain
1343 modesty and dignity at all times. A female sonographer will be provided wherever possible.

1344

1345 MRI scans

1346 MRI is a safe and non-invasive technique with no known risk when appropriately supervised. It does not
1347 involve ionising radiation (X-rays). Potential participants with ferromagnetic objects in their bodies or with
1348 implanted devices which can be damaged by the magnet will be excluded by carefully screening all subjects for
1349 ferromagnetic objects, metal implants and other metal (e.g. shrapnel injury) every time prior to entering the
1350 scanner environment. The University of Oxford Centre for Magnetic Resonance Research (OCMR) is fully
1351 equipped for resuscitation (including defibrillation) in the unlikely event of a medical emergency during
1352 scanning and doctors performing and/or supervising the scans are trained in Advanced Life Support. While
1353 most people do not experience discomfort in a MRI environment, the enclosed space of the scanner can
1354 potentially feel uncomfortable. Discomfort from lying still for a long period will be minimised with
1355 comfortable padding and positioning. People with a history of claustrophobia would be excluded from
1356 participation in the study. Participants will be given a chance to see the scanner before the study starts. Whilst
1357 in the scanner, participants are able to use the alarm button or can squeeze a bulb placed in their hands if they

1358 wish to communicate with the operator or to interrupt the scanning at any stage of the scanning process. As the
1359 MRI scanner is noisy, participants would be fitted with ear-plugs and/or acoustically shielded headphones to
1360 minimize the noise and aid communication between participants and investigators. Participants will be
1361 provided with OCMR scrubs/gowns for the CMR scans that preserve their modesty while remaining loose in
1362 the scanner to avoid potential burns from synthetic clothing. To help maintain participant dignity they will be
1363 asked to leave their underwear on, so long as it has no metal parts (e.g. zips, bra clasps or studs). Participants
1364 will be asked to change in a changing room near to the scanner into OCMR approved clothing and will be
1365 given a locker to securely store their belongings. If they are unable to change into the MRI safe clothing
1366 themselves a member of staff will be on hand to offer assistance.

1367

1368 In the unlikely event of seeing any structural abnormalities on a scan, a clinical specialist will check the scan
1369 and with the inclusion of the kidneys and the brain in the MRI scan, a nominated consultant radiologist has
1370 agreed to review any images where there is concern; and issue a formal report to the patient's GP. If the
1371 specialist feels that the abnormality was medically important, they will discuss the implications with the
1372 participant and arrange for further investigations as necessary. Participants will not be informed unless the
1373 doctor considers the finding has clear implications for their current or future health. It is important to note that
1374 scans are not carried out for diagnostic purposes, and therefore the scans are not a substitute for a clinical
1375 appointment. Rather, the scans are intended for research purposes only.

1376

1377 Gadolinium sub-study

1378 Currently, gadolinium-based contrast agents are widely used in MRI scans to answer important medical
1379 questions, and for advancing scientific discovery and improving clinical care. Gadolinium contrast is widely
1380 used for clinical indications in CMR and is safe to use. Occasionally (< 1 in 1000), it may cause a mild
1381 headache, rash and very rarely a more severe allergic reaction. These severe reactions generally respond very
1382 well to standard emergency drug treatment, similar to that given for other severe allergic reactions. However,
1383 in people with reduced kidney function, it can lead to a rare condition called nephrogenic systemic fibrosis
1384 (NSF); hence, as per departmental SOPs based on Royal College of
1385 Radiologists guidelines, (2007) only research participants with estimated glomerular filtration rate (eGFR)
1386 >30ml/minutes can be given gadolinium. For this study, all potential participants with eGFR
1387 <30ml/minutes will not be recruited. Participants' consent will be sought to obtain a pre-scan blood test to
1388 check kidney function if there is no laboratory blood result for creatinine within the last 6 months prior to
1389 consent, or if investigators make a clinical judgement that a new creatinine result is needed. As explained to the
1390 participant in the PIL, no gadolinium will be given before this result is available. It is known that small
1391 amounts of gadolinium deposits can remain in the body, including the skin, bones and the brain. There has been
1392 no scientific evidence to-date that these gadolinium deposits are harmful or lead to adverse health effects,
1393 although this is an active area of research. If new information relevant to a participant's health becomes
1394 available regarding the use of these contrast agents, a study investigator will discuss this with the participant to
1395 allow them to decide if they wish to continue in the study.

1396

1397 Cardiopulmonary Exercise Testing

1398 Cardiopulmonary exercise testing is very safe and is even used in people with heart failure. However, as with
1399 all forms of hard exercise, very occasionally some people have significant changes in their heart rate and
1400 rhythm that requires medical attention. Although the risk of this happening is small, the test is carried out in a
1401 room equipped with emergency monitoring, emergency medications and resuscitation equipment. Medical
1402 personnel will be available throughout the testing. Participants' heart rate and electrocardiography (ECG) are
1403 monitored throughout the exercise testing and the exercise test will be stopped if there are any concerns. The
1404 study procedures including the cardiopulmonary exercise testing are explained in the Participant Information
1405 sheet and will be made clear to the participants as part of the informed consent process. If there are any
1406 concerns regarding a participant's safety during the exercise testing they will be asked to stop and safety to
1407 continue in the trial will be reviewed by trained and qualified personnel. Doctors who are Advanced Life
1408 Support trained will be available during CPET testing and the site is fully equipped for resuscitation (including
1409 defibrillation) in the unlikely event of a medical emergency during the test.

Reporting

The CI shall submit once a year throughout the clinical trial, or on request, an Annual Progress Report to the REC, HRA (where required), host organisation, funder (where required) and Sponsor. In addition, an End of Trial notification and final report will be submitted to the MHRA, the REC, host organisation and Sponsor.

Participant confidentiality

The study will comply with the General Data Protection Regulation (GDPR) and Data Protection Act 2018, which require data to be de-identified as soon as it is practical to do so. The processing of the personal data of participants will be minimised by making use of a unique participant study number only on all study documents and any electronic database(s), with the exception of the CRF, where participant initials may be added. All documents will be stored securely and only accessible by study staff and authorised personnel. The study staff will safeguard the privacy of participants' personal data.

Expenses and benefits

Reasonable travel expenses for any visits will be reimbursed on production of receipts, or a mileage allowance provided as appropriate. The participants will also be provided with a £30 gift voucher as a 'thank-you' for the time given up, after the final study visit has been completed and the 24hr blood pressure monitor and 7 day activity monitor have been returned to CCRF. The app notifications and usage are free when in WIFI zone but if using 3G/4G they may be charged depending on their network-provider. If this is the case, then any cost incurred will be reimbursed to the participant. Participants in the sub- study will receive a £30 gift voucher as a 'thank you' for the time given up.

18. Finance and insurance

Funding

The research is being financed by a British Heart Foundation Clinical Research Training Fellowship (BHF Grant number FS/19/7/34148).

Insurance

The University has a specialist insurance policy in place, which would operate in the event of any participant suffering harm because of their involvement in the research (Newline Underwriting Management Ltd, at Lloyd's of London). NHS indemnity operates in respect of the clinical treatment that is provided.

Contractual arrangements

Appropriate contractual arrangements will be put in place with all third parties and collaborators

19. Publication policy

The Investigators will be involved in reviewing drafts of the manuscripts, abstracts, press releases and any other publications arising from the study. Authors will acknowledge that the study was funded by the British Heart Foundation Clinical Research Training Fellowship (BHF Grant number FS/19/7/34148). Authorship will be determined in accordance with the ICMJE guidelines and other contributors will be acknowledged. The summarised results will be published in a scientific journal/s and summarised on the CCRF website for participants to read. Should participants wish to have a copy of any papers published, they merely need to contact the study team, using the contact details provided on their PIS, and the team would be happy to provide one.

20. Development of a new product/ process or the generation of intellectual property

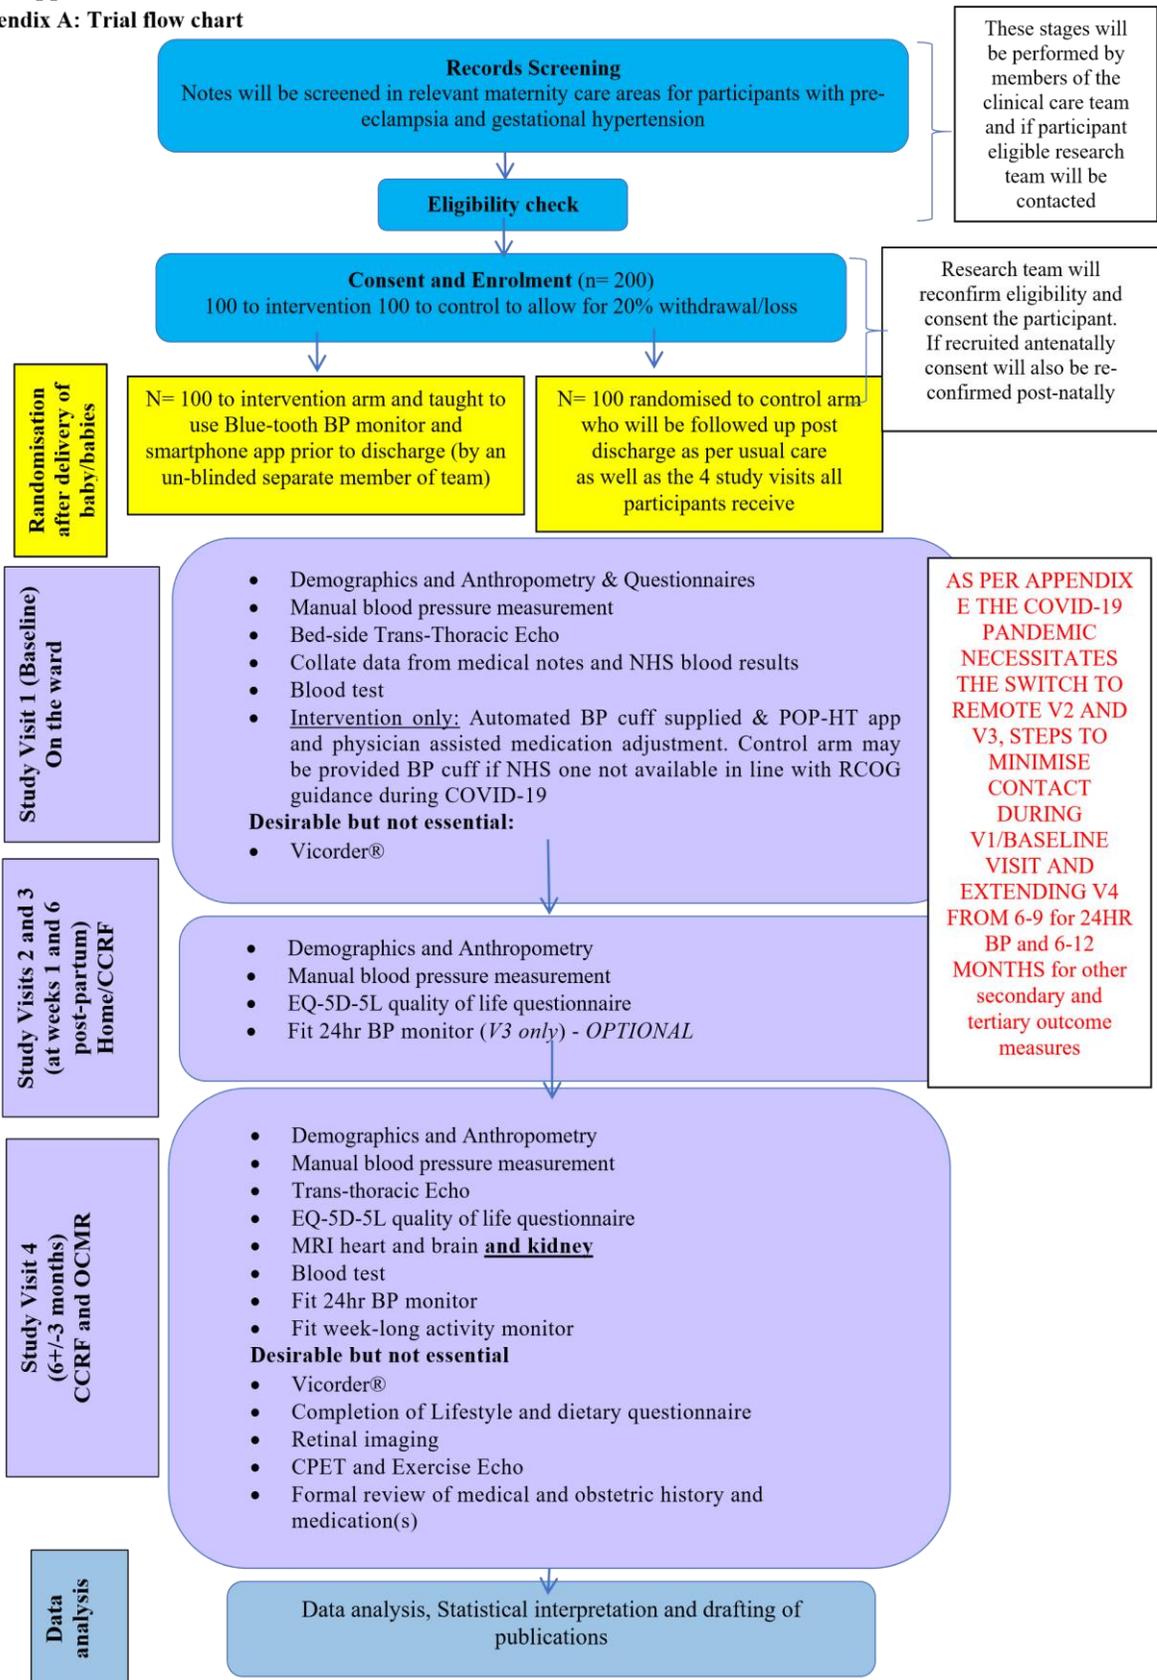

Ownership of IP generated by employees of the University vests in the University. The protection and exploitation of any new IP is managed by the University's technology transfer office, Oxford University Innovations.

1464 **21. Archiving**

1465 Personal data (such as contact details and information, which could identify a participant) will be destroyed as
1466 soon as it is practical to do so and no later than 12 months after the end of the study. The personal identifiers
1467 (name of participant) contained in consent forms and the code break document will be stored or accessed for up
1468 to 10 years after study end, after which time the custodian will agree a date for destruction and it will be
1469 destroyed confidentially. As part of our commitment to maximise patient/service user involvement in research,
1470 participants will give consent (optional) for their contact details to be retained. This will be kept securely and
1471 independently of the study records. This will allow investigators to contact participants about future ethically
1472 approved research.

1473

Appendix D: Estimated duration of each study procedure (main study)

Study visit 1: Baseline	Measure	Time (maximum 75-100 minutes with participant)
	Consent (if not already obtained previously)	30
	Review and confirmation of consent if already obtained previously	5
	Demographics & Anthropometry	10
	Bed-side blood pressure measurement	10
	Bedside Vicorder® (vascular measure) (desirable)	10
	Bedside trans-thoracic echo	15
	Lifestyle and diet questionnaire (desirable and can be completed at a later date)	25
	Collate data from medical notes and NHS blood results (participant not required for this part)	20
	For those randomised to the intervention arm: Automated BP cuff provision and Smartphone app installation by a separate un-blinded team member (once the team performing baseline visit have left the ward)	30
	Blood Sampling/Venepuncture	10
Study visits 2 and 3 at week 1 and 6 postpartum respectively	Measure	Time (~30 minutes per visit)
	Demographics and Anthropometry including reconfirmation of consent	10
	Blood pressure measurement	10
	EQ-5D-5L quality of life questionnaire	5
	Fit 24 hour BP (visit 3 only)	5
Study visit 4: 6 +/- 3 months	Measure	Time (maximum 4 hours)
	Demographics and Anthropometry	10
	Manual blood pressure measurement	10
	Vicorder® (vascular measures) (desirable)	10
	Trans-thoracic Echo	15
	Retinal imaging (desirable)	10
	CPET with Exercise Echo (desirable)	30
	MRI (with blood sampling post scan if consented to late gadolinium and ECV techniques) and MRI safety questionnaire	60
	Fit 24hr BP and activity monitor	10
	Lifestyle and diet questionnaire (desirable)	25
	EQ-5D-5L questionnaire	5
	Review of medical and obstetric history and any medication side effects (desirable)	15

Appendix E: Amendment history

Amendment No.	Protocol Version No.	Date issued	Author(s) of changes	Details of Changes made
01 (minor)	N/A	21/01/2020	J Kitt	Correction to wording of consent form clauses Correction of version listed in flyer footer IRAS form updated to list PI for OUH site
02 (minor)	V2.0	19/03/2020	P Kemp	Add option for Visit 2 (Weeks 1) and Visit 3 (Week 6) to be conducted remotely by video call. Add the option of sending a sterile OMRON EVOLV BP monitor to control arm participants prior to Visit 3 (Week 6). Make the “fitting of a 24-hr home blood pressure monitor” procedure optional for Visit 3 and adding the option of conducting this at a later time point.
03 (minor)	V3.0	22/04/2020	J Kitt and P Kemp	Further changes to visits due to the COVID-19 pandemic: <ol style="list-style-type: none"> 1. Add provision of BP monitor to control arm; 2. Consent process to be modified to reduce risk of transmissions of COVID-19; 3. Extend the time point for Visit 4 to 6-12 months from 6-9 for outcome measures except the primary outcome and BP based secondary outcomes; 4. Change the randomisation and blinding process as only one member of staff (wearing PPE where necessary) can be present at Visit 1; 5. Minimise participant contact during the baseline visit via use of tablets/iPads for reviewing the PIS/flyer; 6. Vicorder is now an optional measurement during the baseline visit.
04 (substantial)	V4.0	06/10/2020	A Frost and P Kemp	Add optional blood test to baseline visit in both control and intervention hypertensive group for 20 participants and include a sub population of 20 normotensive postnatal women for a newly added blood-validation sub study.
05 (minor)	V5.0	05/01/2021	J Kitt and P Kemp	Add option for Visit 4/Final visit to be performed remotely by video call for the primary study outcome and BP based secondary outcome measures

06 (substantial)	V6.0	23/03/2021	J Kitt	<ol style="list-style-type: none"> 1. Addition of an extra 2 minute sequence during the MRI scan to also evaluate the kidneys (T1 maps) 2. Changing the study from a single, blinded RCT to a PROBE design as a result of COVID-19 3. Removal of laser speckle procedure (because it was never carried out on any participants due to COVID-19) as investigator unable to travel to UK 4. Rephrasing of primary objective in line with SAP and published protocol paper with reordering and rephrasing of secondary and tertiary objectives in line with SAP and protocol paper 5. Rephrasing of the wording for those patients have the blood test as part of the endothelial cell sub-study in amendment 4 to make it less ambiguous

1487

1488

1489

Appendix F: Rationale and amendment proposal for restarting POP-HT during COVID-19

1490

The following explanation summarises our reasons to allow the POP-HT RCT to restart during the COVID-19 pandemic, as an exception to Stage 3 of the OUH NHS Foundation Trust guidance. We currently have an exception to Stage 3 for follow up of women already recruited based on the importance of provision of clinical care to these women. Based on our experience during the follow up we believe ongoing recruitment into this trial will allow women in both the intervention and control arm to receive ‘optimal’ clinical care during the current disruption of normal care. This will ensure consistency with adherence to the updated Royal College of Obstetrics and Gynaecology (RCOG) guidance[32] on the care of women during the COVID-19 pandemic within the OUH NHS Trust. Trials of self-monitoring and self-management are safe and effective in other clinical scenarios [33].

1491

1492

1493

1494

1495

1496

1497

1498

1499

Background

1500

Hypertensive pregnancy and risk of complications post-partum - Women who have a pregnancy complicated by preeclampsia/gestational hypertension have a high risk of complications and fluctuations in blood pressure control during the post-partum period that require monitoring. Specific guidance to manage this risk is described

1501

1502

1503

1504

by the Royal College of Obstetrics and Gynaecology (RCOG). However, following such guidance is problematic during a period when access to normal midwife and GP services is reduced, triggering the amendment to their guidance described in point 3 below.

1505

1506

1507

1508

Experience from POP-HT Trial - Based on the first 18 patients recruited to this randomised trial, prior to the COVID-19 pandemic halting recruitment, 10 were randomised to the control arm and 8 to the intervention arm. During the study follow up, 3 of the 10 controls (30%) were identified with elevated readings requiring a change in management, with one being identified with clinical signs (raised JVP and oedema) that required emergency management. In the intervention arm only 1 of 8 (12.5%) required a brief readmission for blood tests and could then be managed with medication up-titration via tele-monitoring and a further 2 of 8 (25%) were managed safely via the proprietary POP-HT app avoiding re-admission.

1509

1510

1511

1512

1513

1514

1515

1516

RCOG guidance during COVID-19: In recognition of the problems with routine clinical review the RCOG have amended their guidance[32] to recommend home BP monitoring (self-monitoring) 2 to 3 times per week for women discharged after a hypertensive pregnancy. Take up of this guidance has been sporadic because of the change in practice and requirement for additional equipment (blood pressure monitors) this advice necessitates.

1517

1518

1519

1520

1521

1522

1523 Rationale for restart of POP-HT

1524 Provision of guideline clinical care in control and intervention arm during pandemic - POP-HT provides access
1525 to ongoing post-partum care for women after an episode of preeclampsia. This is either consistent with current
1526 RCOG guidance on usual care in the absence of ‘normal’ midwife and GP care with provision of blood
1527 pressure monitors (control arm) or an enhanced level of clinical care with additional remote, physician
1528 optimised selfmanagement (intervention arm).

1529
1530 Reduced need for hospital attendance during pandemic through participation in trial – Current early data, and
1531 previous work within a pilot study, indicates the intervention arm have a lower incidence of hospital attendance
1532 reducing risk for contracting COVID-19 for both mother and child in this arm. This requires validation in the
1533 full study but would be a secondary benefit for some participants within the trial, if consistent. In addition,
1534 review assessments that form part of the research study protocol for both control and intervention arms allows
1535 clinical assessments to identify onset of problems or reassure safety to remain at home. These assessments
1536 replicate some of the ‘normal’ GP and midwife care that is currently difficult to deliver.

1537

1538 Safety of proposal to re-start

1539 Remote study visits already established - To manage follow up at the start of the pandemic the study was
1540 amended to allow entirely remote follow up visits for week 1 and week 6, equivalent to visits 2 and 3
1541 (nonsubstantial amendment 2.0 25/03/2020). Over the past 6 weeks trialling of remote follow up has been
1542 undertaken and shown to be effective and feasible. No participants have required face-face contact while
1543 review of medication, use of the POP-HT app and remote blood pressure measurement (both clinic and
1544 ambulatory 24hr blood pressure monitoring) has been achieved for all participants.

1545

1546 Proposed amendment of baseline visit – No new baseline visits have yet been performed during the COVID-19
1547 pandemic but we have re-designed the recruitment, consent and enrolment process to minimises direct patient
1548 contact and risk of virus transmission:

- 1549 • Provision of documents: PIS, flyer and additional information sheet will all be provided by the clinical
1550 team to the participant on a Tablet/ipad® (sterilised with CLINELL® wipes). The participants can
1551 then review them in this format (and a copy will be e-mailed to them for their records once consent
1552 has been obtained and they are enrolled).
- 1553 • Consent: Consent forms will be placed in wipe down wallets, which will be handed to the participant
1554 for signing wearing sterile gloves. Once signed the form will be photocopied whilst wearing gloves.
1555 The copy will then be placed back into a sterile wallet for the participant and the original will be
1556 placed in a second wallet. Both will be wiped down with CLINELL® wipes and the research teams’
1557 copy will be kept securely in a wipe-down file/ring-binder in ‘quarantine’ before moving them to
1558 CCRF after 48hours.
- 1559 • The Vicorder® is now an optional measurement
- 1560 • The Echo and Vicorder® will now be performed by a single investigator (Dr Jamie Kitt) at the
1561 bedside. PPE will be used where necessary in line with hospital policy. Adequate training in donning
1562 and doffing of PPE has been undertaken by Dr Kitt via OXSTAR who delivered training to OUH NHS
1563 Staff (Train the Trainer Course). This will not affect OUH trust protocols for female chaperones,
1564 which can still be provided if needed by existing clinical staff on the ward.

1565

1566 Summary

1567 The reduced level of routine care during the COVID-19 pandemic introduces significant variation into the
1568 clinical care of women who have had preeclampsia or gestational hypertension who are at risk of complications
1569 after discharge from secondary care. We believe that restarting recruitment into POP-HT will provide, at the
1570 minimum the recommended standard of clinical care advocated by the updated RCOG guidance[32] within the
1571 control arm, as well as the planned trial of more enhanced care within the intervention arm. The trial has
1572 already been adapted, with tests of feasibility, to allow remote follow up and careful consideration has been
1573 given to the effective and safe restart of baseline visits.

1659 **2. Introduction**

1660 **Preface**

1661 Chief Investigator: Prof Paul Leeson

1662 Supervisors: Prof Richard McManus, Prof Paul Leeson, Dr Adam Lewandowski

1663 Supervising Trial Statistician (s): Dr Jill Mollison and Dr Milensu Shanyide

1664 Study title: Physician Optimised Post-partum Hypertension Treatment trial

1665 Short title: POP-HT TRIAL

1666 Ethics reference: 19/LO/1901

1667

1668 **Purpose and scope of the plan**

1669 This document details the proposed presentation and analysis for the main paper (s) reporting results of the
 1670 POP-HT trial. The results reported in these papers should follow the strategy set out here. Subsequent analyses
 1671 of a more explanatory nature will not be bound by this strategy, although they are expected to follow the broad
 1672 principles laid down here. The principles are not intended to curtail exploratory analyses (for e.g. to decide cut
 1673 off points for categorisation of continuous variables), nor to prohibit accepted practices e.g. data transformation
 1674 prior to analysis, but they are intended to establish the rules that will be followed, as closely as possible, when
 1675 analysing and reporting the trial.

1676

1677 The analysis strategy will be available on request when the principal papers are submitted for publication in a
 1678 journal. Suggestions for the subsequent analyses by journal editors or referees, will be considered carefully,
 1679 and carried out as far as possible in line with the principles of this analysis strategy, if reported, the source of
 1680 the suggestion will be acknowledged.

1681

1682 This version of the Statistical Analysis Plan was written based on protocol version 6.0 23/03/2021.

1683

1684 **Objectives**

1685 The trial is a single centre, Prospective Randomised Open Blinded End-point (PROBE) study. Women who
 1686 develop hypertensive disorders of pregnancy, which require on-going treatment for blood pressure after birth at
 1687 the time of discharge, will be randomised to one of two treatment arms: usual care, or self-management of
 1688 blood pressure. Women will be recruited from the John Radcliffe Hospital and this study will investigate the
 1689 effectiveness of post-partum physician assisted self-management of blood pressure vs standard care over the
 1690 first 6 (up to 9) months post-partum, although the time point for analysis of the secondary outcome measures
 1691 was extended up-to 12 months post-partum as a result of the COVID19 pandemic as part of a protocol
 1692 amendment (see table A1).

1693

	Objectives	Outcome Measures	Timepoint(s)
Primary	To compare diastolic BP in the intervention arm to the control arm post-partum.	24 hour average diastolic BP measured by SPACELAB 90217 24hr Ambulatory blood pressure monitoring (ABPM)	Primary timepoint at 6 months

Secondary	To compare the effect of the intervention on cardiovascular, cerebrovascular and vascular phenotypes	<p><u>BP based</u></p> <ul style="list-style-type: none"> a) 24 hr average systolic blood pressure assessed by SPACELAB 90217 24hr ABPM b) Mean diurnal diastolic blood pressure assessed by SPACELAB 90217 ABPM c) Mean diurnal systolic blood pressure assessed by SPACELAB 90217 ABPM d) Mean nocturnal diastolic blood pressure assessed by SPACELAB 90217 24hr ABPM e) Mean nocturnal systolic blood pressure assessed by SPACELAB 90217 24hr ABPM f) Mean bedside diastolic blood pressure measured during study visit (mean of 2+3) g) Mean bedside systolic blood pressure measured during study visit (mean of 2+3) <p><u>Cardiac MR</u></p> <ul style="list-style-type: none"> h) Left ventricular (LV) mass indexed to end-diastolic volume and body surface area (BSA) i) LV EDV indexed to BSA j) LV wall thickness (MRI) – septum, posterior and RWT k) LA volume indexed to BSA l) Right ventricular (RV) mass indexed to end-diastolic volume and body surface area (MRI) m) RV EDV indexed to BSA n) RA volume indexed to BSA o) LV ejection fraction (EF) & RV EF p) LV and RV stroke volumes indexed to BSA q) Myocardial fibrosis (for those in gadolinium sub-study) r) ECV (for those in gadolinium substudy)) <p><u>Echo</u></p> <ul style="list-style-type: none"> s) LV Diastolic function: E/E’ average, E/A ratio, E deceleration time. t) Global longitudinal strain (GLS) u) LV wall thickness (Septal, posterior and RWT) v) LV systolic function (EF by Biplane Simpsons) w) LA volume by Biplanar assessment <p><u>Vascular:</u></p> <ul style="list-style-type: none"> x) Pulse wave velocity 	<p>Weeks 6 and 6months for the 24 hr ABPM</p> <p>Baseline, week 1, 6 and 6months for the bedside blood pressures</p> <p>For Cardiac MR at 6 months</p> <p>At baseline and at 6 months postpartum for Echo outcome measures</p> <p>PWV, Aortic BP and AI at baseline and at</p>

	in intervention vs control arm Side-effect impact	Readmission number in each arm Number and frequency of side-effects reported (intervention via the app and control during follow up calls/SMS)	12 months postpartum 12 months postpartum
Intervention(s)	The intervention will consist of physician-optimised self-management of post-partum BP. Women will follow a ‘smartphone’ app based algorithm for medication-titration, which will provide individualised dose titration advice. This is overseen and any change is approved by physicians who can review the uploaded readings and respond to telemonitored abnormal readings in a timely fashion.		
Comparator	The control arm will be managed as per usual NHS led care with assessment by their own health care professionals and adjustment of their medications as is needed. The BP of this group will be monitored and recorded at the same time-points and in the same manner as the intervention arm as will all other secondary outcome measures.		

1694

1695

1696

Blood validation sub-study

1697 We aim to recruit 20 normotensive participants as a reference population for endothelial function to compare
1698 with the endothelial function of 20 of the 200 hypertensive participants recruited into the mainstudy. The
1699 purpose of the sub study is to provide a reference population of women not affected by hypertensive disease.
1700 In the sub study, healthy postnatal women will undergo measurements of specific characteristics of blood
1701 cells and circulating factors involved in inflammation and endothelial dysfunction. This population will
1702 validate how blood cells and circulating factors vary naturally and may be affected by external factors such as
1703 mode of delivery.

1704

1705

1706

3. Trial design

1707 The trial is a single centre, Prospective Randomised Open Blinded End-point (PROBE) study. Women who
1708 develop hypertensive disorders of pregnancy, which require on-going treatment for blood pressure after birth at
1709 the time of discharge, will be randomised to one of two treatment arms: usual care, or self-management of blood
1710 pressure. Women will be recruited from the John Radcliffe Hospital and this study will investigate the
1711 effectiveness of post-partum, physician assisted self-management of blood pressure vs standard NHS care in the
1712 post-partum period.

1713

1714

Main trial setting and participant profile

1715 We aim to recruit 200 participants of which we will randomise 100 to the intervention arm and 100 to the
1716 control arm. The intervention arm will comprise tele-monitored home blood pressure monitoring (including
1717 periods of home 24hr ABPM) coupled with physician-assisted self-management. The control arm will receive
1718 ‘standard’ levels of NHS care from their GP and midwives and health visitors. All participants will be
1719 recruited from the Oxford Women’s Centre at the John Radcliffe Hospital, which sees approximately 25
1720 patients per month with hypertensive pregnancies.

1721

1722 **Main study visit and measures**

1723 The expected duration of participant involvement will be 6 (up to 12) months from enrolment to study
1724 completion and participants will be asked to attend four study visits after their pre-screening and enrolment:
1725 baseline, at 1 week, at 6 weeks and at 6 months. At times when face to face appointments are restricted due to
1726 regulations related to the COVID-19 pandemic, the week 1 and week 6 visits can be done remotely where
1727 needed to avoid putting participants at undue risk. The primary outcome will be studied over the narrower time
1728 frame of 6-9 months as originally described at the study outset, even during the COVID-19 pandemic, but a
1729 further amendment (see table A1 of supplementary material) allows all BP based primary and secondary
1730 outcomes to be done remotely, if needed. The other secondary outcomes can be done over a wider timeframe of
1731 6-12 months to allow participants to safely attend their study visit at the hospital.

1732

1733

1734 **4. Definition and derivation of outcome measures**

1735 **Primary outcome**

1736 The primary outcome for this study is the 24-hour overall average diastolic blood pressure (mmHg) at the
1737 final visit (V4), assessed by SPACELAB 90217® 24hr Ambulatory blood pressure monitor adjusted for clinic
1738 (i.e. bedside) baseline diastolic BP at the time on enrolment.

1739

1740 Derivation: When performing a 24hr BP monitor, cuff size is checked before fitting the monitor on the mid-
1741 left arm and an appropriate cuff size is fitted, in a standardised manner. BP Data is automatically recorded at
1742 30 minute intervals between 7am and 10pm and at 60 minute intervals from 10pm to 7am.

1743 Diurnal readings are defined as those between 0700-2200 and nocturnal from 2200-0700 for consistency. The
1744 monitor is fitted during the V4 at 6 months post-partum.

1745

1746 All monitors are programmed to be 'silent' as well as to not show participants the value of the readings to
1747 minimise any white coat/alerting response. Participants complete a standardised diary sheet to record sleep
1748 and awake times and any periods of exercise that could confound readings. Data are uploaded from the
1749 monitor to SPACELABS proprietary SENTINEL® software, which produces a standardised report of 24
1750 hour overall diastolic and systolic readings with standard deviations (SD), daytime/awake diastolic and
1751 systolic readings with SDs and nocturnal diastolic and systolic readings with SDs. Any manual readings
1752 (which can be obtained by pushing the blue button on the 24 ABPM device) accidentally, or when the device
1753 is first fitted to confirm adequate placement, are excluded from the analysis and these are automatically
1754 flagged and removed by the software. Any readings corresponding as 'exercise' or as a 'daytime nap', as
1755 exemplified on the sample diary sheet included at the end of the SAP, during the period of recording are also
1756 excluded.

1757

1758 NICE guideline (NG136)[34] states that at least 2 measurements per hour are taken during the person's usual
1759 waking hours and the average value of at least 14 measurements are to be taken during the person's usual
1760 waking hours for a monitoring period to be valid. In cases where this is not achieved, women will be asked to
1761 repeat the monitor as soon as possible and within the stipulate time frames laid out in the protocol (i.e. for V4
1762 the time period is 6-9 months post-discharge). In cases where repeat monitors are needed, a blinded
1763 investigator will then analyse the data from both sets of 24hr monitoring periods to obtain: 24 hour overall
1764 diastolic and systolic readings with SDs, daytime/awake diastolic and systolic readings with SDs deviations,
1765 and nocturnal diastolic and systolic readings with SDs. If unable to obtain a repeat set of readings a blinded
1766 adjudication committee will be decided to determine whether to include/exclude the first set of readings and if
1767 so, whether diurnal, nocturnal, all or none. In such cases included, the data will be starred and referenced to
1768 explain the number of participants with incomplete 24hr BP data.

1769

1770 24hr BP Data is exported from SENTINEL® to CASTOR®, an electronic CRF system, by an independent
1771 investigator, and from there it can be exported for analysis by the study statistician, who is masked.

1772

1773 **Secondary outcomes**

1774 Statistical analysis of the secondary outcomes will be performed blind to treatment allocation. Imaging
1775 variables, because of their known operator variability will be subject to an inter-operator variability check in
1776 10-20% of cases i.e. the analysis of 10-20% will be repeated by a 2nd independent, member of the team at

1777 random, and data will be presented on inter-user variability e.g. For echo assessment of LV function, LA
1778 volume and MRI assessment of LV and RV volumes.

1779

1780 The time frames stipulated in the protocol for the 24hr BP based secondary outcomes are as follows: for V3
1781 the data will be collected at 6 weeks (+/- 5 days post discharge) and for V4, data will be collected at 69
1782 months post-partum.

1783

1784 24hr BP monitor based secondary outcomes:

1785 • 24 hr average systolic blood pressure assessed by SPACELAB 90217 24hr Ambulatory blood
1786 pressure monitoring at the V3 and V4

1787 • Mean diurnal diastolic blood pressure assessed by SPACELAB 90217 24hr Ambulatory blood
1788 pressure monitoring at the V3 and V4

1789 • Mean diurnal systolic blood pressure assessed by SPACELAB 90217 24hr Ambulatory blood
1790 pressure monitoring at the V3 and V4

1791 • Mean nocturnal diastolic blood pressure assessed by SPACELAB 90217 24hr Ambulatory blood
1792 pressure monitoring at the V3 and V4

1793 • Mean nocturnal systolic blood pressure assessed by SPACELAB 90217 24hr Ambulatory blood
1794 pressure monitoring at the V3 and V4

1795

1796 N.B. Please refer to the Derivation section for the primary outcome, for what constitutes a diurnal and nocturnal
1797 readings on a 24hr BP monitor and for further details on their derivation.

1798

1799 Bedside BP based secondary outcomes:

1800 For the bedside BP outcomes listed below, the three blood pressure readings will be obtained from the left
1801 arm as described in the protocol paper during each study visit i.e. a participants will have their blood pressure
1802 checked using the automated mode of a validated, calibrated sphygmomanometer. Three blood pressure
1803 readings will be taken at intervals of 1 minute. The first reading will be discarded and the 2nd and
1804 3rd reading used to calculate the mean blood pressure. The measurement technique advised by the British
1805 Heart Foundation will be strictly followed i.e. BP will be measured after 5 minutes' rest with the participant
1806 sat/laying at 45 degrees. They will be asked not to talk and, the arm will be supported and cuff positioned at
1807 the height of the heart, with their legs uncrossed. V2 takes placed at 7 +/- 5 days, V3 at week 6 +/-5 days
1808 following discharge and V4 at 6-9 months post-partum.

1809 • Mean bedside diastolic blood pressure, measured during the study visits (mean of readings 2+3) at
1810 V2, V3 and V4

1811 • Mean bedside systolic blood pressure measured during study visit (mean of readings 2+3) at V2, V3
1812 and V4.

1813

1814 If a participant does not complete the study visit e.g. they miss their week 1 follow up then no data will be
1815 included for that participant for that timepoint. Mean data for each time-point will only be reported where
1816 complete data is available e.g. All 220 participants recruited have blood pressure data from their baseline
1817 visit, but if 20 patients are lost to follow up/withdrawn by V4 then only 200/220 will be reported and this will
1818 be highlighted in the relevant table. All BP data is entered in real-time during each study visit into CASTOR
1819 edc®. Data-cleaning and export will be done by a blinded study investigator.

1820

1821 Additional analysis on the BP secondary outcome measures:

1822 Potential confounding factors for the blood pressure values are collected during the period of enrolment from
1823 baseline to the time of V4 completion. These include questionnaire based self-reported salt intake
1824 (low/moderate or high), alcohol intake (number of units), smoking history, BMI and objectively recorded
1825 activity levels (measured by a validated wrist-worn accelerometer). These will be described per randomised
1826 group and differences between groups will be estimated using a mean difference and 95% confidence
1827 intervals.

1828

1829 Other secondary outcome measures:

1830 For the remainder of the secondary outcomes, due to the impact of COVID, protocol amendments (see table
1831 A1 of supplementary material) were submitted, and approved, to extend the time-frame for the outcomes
1832 listed below to 6-12 months post-partum. Where possible all data is acquired in the same visit but if patients
1833 are unwilling to attend the hospital during national lockdowns or due to COVID concerns, the primary and
1834 BP based secondary outcomes will be done remotely or as a home visit; the secondary outcomes below are
1835 collected at a later date at the hospital within the 6-12 month window post-partum.

1836

1837 Cardiac MRI based:

- 1838 • Left ventricular (LV) mass indexed to end-diastolic volume and body surface area
1839 (LVMI/EDV/BSA; g/ml/m²) during the V4,
- 1840 • LV end-diastolic volume (EDV) indexed to body surface area (LV EDV/BSA; ml/m²); during the V4
- 1841 • LV wall thickness indexed to BSA – septum, posterior and RWT (mm/m²); during the V4
- 1842 • Left atrial (LA) volume indexed to BSA (ml/m²); during the V4
- 1843 • Right ventricular (RV) mass indexed to end-diastolic volume and body surface area
1844 (RVMI/EDV/BSA; g/ml/m²); during the V4
- 1845 • RV end-diastolic volume (EDV) indexed to body surface area (RV EDV/BSA; ml/m²); during the V4
- 1846 • Right atrial (RA) volume indexed to BSA (ml/m²); during the V4
- 1847 • LV ejection fraction (EF) and RV EF (absolute percentage (%)); during the V4 • LV and RV
1848 stroke volumes indexed to BSA (ml/m²); during the V4

1849

1850 All measurements will be performed using CIRCLE® CVI42 proprietary software and downstream analysis
1851 of the MRI images will be done by a fully blinded investigator. Height (cm) and weight (kg) is obtained using
1852 the same calibrated scales immediately prior to the MRI (when wearing same departmental scrubs and no
1853 shoes) in order to calculate body surface areas (BSA) by Mostellar equation.

1854

1855 An optional sub-study involving administration of Gadolinium contrast will be offered as an additional
1856 component to the MRI, in those women who are not breast feeding. This is part of exploratory work that may
1857 feed into a larger future trial and outcomes related to this sub-study include:

- 1858 • Myocardial fibrosis – this will be described as the overall number of participants in each group with
1859 any degree of myocardial fibrosis and also the number with each pattern of fibrosis e.g. midwall
1860 band, patchy enhancement of the RV/LV junction, epicardial.
- 1861 • ECV (extra-cellular volume) will be derived with regions of interest drawn pre- (A) and postcontrast
1862 (B) agent with the equation: myocardial ECV = (1 – Haematocrit) ×
1863 ($\Delta R1_{\text{myocardium}}/\Delta R1_{\text{blood}}$), where $R1 = 1/T1$. The post-contrast map will be obtained 15 min post-
1864 Gadovist® contrast bolus. The Haematocrit is obtained immediately prior to the MRI scan during
1865 cannulation.

1866

1867 Echo measures:

1868 All echo images are obtained as part of a standard BSE echo dataset. The V1 (baseline visit) is done on the postnatal
1869 ward prior to discharge as described in the protocol paper.

1870 The following measures of systolic and diastolic function will be assessed:

- 1871 • E/E' average; at the baseline visit (V1) and at the final visit (V4)
- 1872 • E/A ratio; at the baseline visit (V1) and at the final visit (V4)
- 1873 • E deceleration time; at the baseline visit (V1) and at the final visit (V4)
- 1874 • LV systolic function (ejection fraction by Biplane Simpson's method); at the baseline visit (V1) and
1875 at the final visit (V4)

1876

1877 Echo will also be used to assess:

- 1878 • Left atrial (LA) biplanar volume; at the baseline visit (V1) and at the final visit (V4)
- 1879 • Septal wall, posterior wall and relative wall thickness indexed to BSA (mm/m²); at the baseline visit
1880 (V1) and at the final visit (V4)

1881 • Global longitudinal strain (GLS); at the baseline visit (V1) and at the final visit (V4)
1882
1883 All echo-based image analysis will be performed using Philipps ISCV® and TOMTEC® proprietary software
1884 and analysed in line with British Society of Echo (BSE) guidelines. All image analysis will be done on fully
1885 de-identified images so that no allocation is known at the time of analysis.
1886

1887 Vascular measures:

- 1888 • Pulse wave velocity (m/s); at the baseline visit (V1) and at the final visit (V4)
- 1889 • Augmentation index (%); at the baseline visit (V1) and at the final visit (V4)
- 1890 • Aortic BP (mmHg); at the baseline visit (V1) and at the final visit (V4)
- 1891 • Aortic distensibility (MRI) at the single time-point of 6-12 months post-partum

1892
1893 During the final visit (V4) aortic BP, PWV, AI measures are obtained whilst the patient remains in the MRI
1894 scanner in the same time, and position, that the aortic cine images are obtained by the cardiac MRI scanner.
1895

1896 Cerebrovascular measures:

- 1897 • Total white matter hyper-intensity volume indexed to BSA (μm^2) during the final study visit (V4)
- 1898 • Cerebral blood flow (ml/s) during the final study visit (V4)
- 1899 • Mean vessel thickness of the middle and posterior cerebral arteries and internal carotid artery (mm)
1900 during the final study visit (V4)

1901
1902 Retinal measures:

- 1903 • The corrected central retinal arteriolar equivalent during the final study visit (V4)
- 1904 • The corrected central retinal venular equivalent during the final study visit (V4)
- 1905 • Corrected central retinal arteriolar equivalent/corrected central retinal venular equivalent ratio during
1906 the final study visit (V4)

1907
1908 Exercise echo measures:

- 1909 • Exercise ejection fraction (echo) at 50% of predicted peak workload (based on their age and resting
1910 heart rate). This will be monitored during a bicycle cardio-pulmonary exercise test (CPET) and the
1911 baseline EF (%), exercise EF (%) and percentage changed will be presented as a mean and standard
1912 deviation. This measure is done at a single time-point during the final study visit (V4).
- 1913 • Exercise LA volume will be measured at 50% of their predicted peak workload based on their age
1914 and resting heart rate. This will be monitored during a bicycle cardio-pulmonary exercise test
1915 (CPET) and the baseline LA volume (ml/m^2), exercise LA volume (ml/m^2) and the percentage
1916 changed will be presented as a mean and standard deviation . This measure is done at a single time-
1917 point during the final study visit (V4).

1918
1919 Cardiopulmonary exercise test measures:

- 1920 • The VO_2 at VT1 (litres/minute) be measured (during a continuously monitored bicycle CPET
1921 starting at 20W and increasing by 15W/minute in a RAMP protocol). The VO_2 (l/min) will be
1922 presented as a mean and standard deviation in each group.

1923
1924 **Tertiary outcomes**

- 1925 • EQ-5D VAS score and index value will be presented as a mean and standard deviation in each
1926 allocation (intervention and control), for each study visit, at each timepoint from baseline to the final
1927 V4.
- 1928 • Readmission number in each arm; will be reported as an absolute number per each allocation.
- 1929 • Number of side-effects reported (intervention reporting via the app; and control during follow up
1930 calls/SMS/medical records), will be reported as number of side effects per person and/ or the n (%)
1931 of participants with at least 1 side effect.

1932

1933 There are a number of exploratory tertiary outcomes including:

1934 • T1 mapping of the kidneys to look at cortico-medullary differentiation of a sub-set of individuals as
1935 part of a protocol amendment. T1 values will be reported as a mean and standard deviation for each
1936 group.

1937 • The blood validation sub-study. The outcome measure for this sub-study will be biomarker levels
1938 associated with endothelial dysfunction, which will be reported at baseline and at 6-12 months as a
1939 mean and standard deviation for each arm (hypertensive vs normotensive).

1940

1941 **Target population Inclusion**

1942 criteria

1943 • Participant is willing and able to give informed consent for participation in the trial.

1944 • Female, aged 18 years or above.

1945 • Clinician confirmed diagnosis of either gestational hypertension or pre-eclampsia defined by NICE
1946 NG 133[34]

1947 • Requiring anti-hypertensive medication at the point of discharge from secondary care.

1948 • Participant has clinically acceptable laboratory results and clinical course post-partum with no other
1949 adverse complicating factor requiring prolonged admission post-partum that would make
1950 participation unfeasible as judged by the CI. Examples would include stroke sequelae, ongoing DIC,
1951 the baby/babies requiring prolonged NICU/SCBU admission of >1 week.

1952 • In the Investigator's opinion, is able and willing to comply with all trial requirements including
1953 ownership of a 'Smart-phone/Tablet' and willing to use the smart-phone app if randomised to that
1954 arm.

1955 • Sufficient competence in English Language to follow the app instructions and partake in the study, as
1956 judged by the CI

1957

1958 Exclusion criteria

1959 The participant may not enter the study if ANY of the following apply:

1960 • Significant renal or hepatic impairment that would affect safe medication titration and adjustment as
1961 part of the trial, as deemed by the Investigator.

1962 • Participant with life expectancy of less than 6 months.

1963 • Any other significant disease or disorder, which, in the opinion of the Investigator, may either, put
1964 the participants at risk because of participation in the trial, or may influence the result of the trial, or
1965 the participant's ability to participate in the trial.

1966 • Participants who have participated in another research trial involving an investigational product in
1967 the past 12 weeks.

1968 • Women with pre-existing hypertension (essential hypertension) will be excluded, as this is a separate
1969 pathology that would affect the efficacy of the study intervention and affect the primary and
1970 secondary outcomes of the study.

1971

1972 An absolute contra-indication to MRI (as per MRI safety questionnaire) precludes them partaking in the MRI
1973 but not in the remainder of the study

1974

1975 Additional exclusion criteria specific to the Gadolinium sub-study are:

1976 • Breast feeding, • eGFR <30ml/minute.

1977

1978 **Sample size**

1979 Power calculations to determine adequate sample sizes for this trial are summarised below:

1980

1981 Primary outcome measure: 24-hour average diastolic blood pressure (mmHg) at 6-9 months post-partum as assessed by
1982 SPACELAB 90217 24hr Ambulatory blood pressure monitor

1983

1984 Sample size calculation: The detection of BP differences between the 2 arms of this trial is based on the mean
1985 diastolic blood pressure difference detected in the pilot SNAP-HT study at 6 months. The mean BP difference
1986 detected between the intervention and control arm at the 6 month time-point was -4.5mmHg. We have used a
1987 more conservative standard deviation (SD) of 10mmHg in each arm (in SNAP-HT the SD was 8.2mmHg in the
1988 intervention arm and 9.8 mmHg in the standard care arm[4]) and 10mmHg SD is in keeping with pooled SDs
1989 for ambulatory diastolic blood pressure readings from other studies. To detect a treatment effect on diastolic
1990 blood pressure of -4.5mmHg, powered to 80% at $p=0.05$ requires a total sample size of 158 and with 1:1
1991 randomisation this would require 79 in each arm. We adjusted our power calculations to determine the final
1992 sample size, to allow for up to 20% loss to follow up/withdrawal based on prior experience. Thus, we aim to
1993 recruit 100 to the intervention and 100 to the control arm.

1994

1995 During COVID-19 a Royal College of Obstetricians and Gynaecology (RCOG) guideline[32] was issued that
1996 recommended a home BP monitor be given to all women for the first week after discharge. As a result of the
1997 potential dilution of the effect size that self-monitoring in the control group could have, we recalculated our
1998 sample size. A systematic review [35] concluded that self-monitoring in the control could lead to a potential
1999 0.42mmHg dilution of the impact of self-management on diastolic BP at 6 months, measured using 24hr ABPM.
2000 Therefore, assuming the same SDs of 10mmHg in each arm as in our original submission to the BHF, we
2001 subtracted 0.42mmHg from the 4.5mmHg between group difference we had originally powered on. To remain
2002 powered at $> 80\%$ and we would require 95 in each group (190 total) and hence we planned to over-recruit to
2003 220 (rather than the original 200) to allow for a larger withdrawal/loss to follow up rate in light of this.

2004

2005 Secondary outcome hypothesis: Improved blood pressure control in the post-partum period (0-9 months) in POP-HT
2006 will result in improved cardiac, vascular and cerebrovascular phenotypes during the V4.

2007

2008 Secondary outcome power calculations:

2009 • Cardiac MRI: Studies using echocardiography by our collaborators have compared BP and LV mass in
2010 pre-eclampsia patients and control patients, at 1 year post-partum [19, 31][19, 31][19, 31][19, 31][19,
2011 31][19, 31]. They found that a difference in BP at 1 year of 10mmHg in diastolic BP corresponded to
2012 significant differences in LV mass. SNAP-HT appeared to achieve a 50% reduction of anticipated BP
2013 difference seen between pre-eclamptic and normotensives at 1 year by 6 months i.e. ~5mmHg. If it is
2014 assumed that the structural/phenotypic benefit results from the BP benefit, as we are hypothesising,
2015 then we must power to detect 50% of the phenotypic difference. In previous work by our group we
2016 have demonstrated significant differences in LV mass/EDV (g/ml) in a similar age and predominantly
2017 female population with similar mean diastolic BP differences between groups to that seen in SNAP-
2018 HT. The LV mass/EDV (g/ml) in the group with high normal blood pressure was 1.54g/ml vs. 1.22
2019 g/ml in those with optimal blood pressure with a standard deviation of 0.33 and 0.27 respectively at
2020 $P<0.001$. Based on these assumptions, to observe a treatment effect of 0.16 (50% of the difference
2021 between 1.54g/ml and 1.22g/ml) on LV mass/EDV, requires 67 in the intervention arm and 67 in the
2022 control arm (132 total). This is calculated using the larger SD of 0.33 referenced above at a power of
2023 $>80\%$ to detect a difference between the groups at $p=0.05$. This number should take into account for
2024 the greater dropout rate we may see for the MRI outcomes.

2025

2026 • Cerebrovascular MRI : Work by our group [17], on pre-eclamptic pregnancy, showed an increased
2027 burden of temporal lobe white matter lesion volume 5-10 years after a pre-eclamptic pregnancy
2028 ($23.2\pm 13 \mu\text{l}$) vs matched individuals who had a normotensive pregnancy ($10.9 \pm 11.5 \mu\text{l}$) at
2029 $p<0.05$. If we again assume we can detect a 50% of the phenotypic benefit with our intervention as
2030 outlined above, we would anticipate a 50% reduction in the burden of white matter lesions i.e.
2031 $6.15 \mu\text{l}$ (50% of $23.2 - 10.9 \mu\text{l}$) in the intervention arm. With 71 in the intervention group and 71 in
2032 the control group (142 total), this will provide $>80\%$ power at $p=0.05$, even using the more
2033 conservative SD of 13ul to detect a 50% improvement in white matter lesion volume between the
2034 intervention and the control group. This number should take into account for the greater dropout rate
2035 we may see for the MRI outcomes.

2036

- 2037
- 2038
- 2039
- 2040
- 2041
- 2042
- 2043
- 2044
- 2045
- 2046
- 2047
- Aortic compliance: Several studies assessing the impact of blood pressure on aortic compliance have shown that even modest reductions in systolic/diastolic blood pressure increase aortic distensibility/compliance[36]. One such study had a mean difference in systolic blood pressure of 4.6mmHg between the 2 drug treatment arms at 52 weeks, akin to the same mean difference in SNAP-HT at 6 months, albeit this was diastolic not systolic, although other studies have suggested diastolic BP may be even more important in influencing aortic compliance. In this study with a mean 4.6mmHg difference in systolic BP there was a treatment difference of 0.12 [36] [(95% CI -0.35, 0.60), $P = 0.60$ in aortic compliance. Based on these assumptions, to observe a treatment effect from our intervention, with 100 in the intervention and 100 in the control arm we will be more than powered at >90% to detect a difference at $P=0.05$ in POP-HT.
- Exercise ejection fraction: Huckstep et al [37] from our group compared resting and exercise ejection fractions for young adults with high normal BP vs. a normotensive cohort. The cohort was very well matched demographically to our planned study cohort, albeit it included both males and females. Resting ejection fraction (by Biplane Simpson's) was similar between groups but at 40%60% of peak exercise intensity, the higher blood pressure group had a lower exercise ejection fraction than the normotensive cohort (73.9 ± 3.25 vs. $80.0 \pm 4.54\%$, $p < 0.001$) and in keeping with this, a smaller increase in ejection fraction when going from baseline to 40% exercise intensity (10.4 ± 5.92 vs. $19.0 \pm 6.90\%$, $p < 0.001$). Assuming the ~5mmHg mean BP improvement achieved in SNAP-HT again translates to a 50% phenotypic benefit, when assessing exercise ejection fraction we anticipate a 4.3% improvement in exercise stress ejection fraction in the intervention arm vs. the control arm (4.3% is 50% of the difference i.e. 50% of 10.4-19%). With 43 participants in the intervention arm and 43 in the control arm (86 total) we will be powered at >80% to detect such a difference at $p=0.05$, which will take account of the lower number likely to undertake the CPET at the final study visit.

2062 5. Analysis – General considerations

2063 Descriptive statistics

2064 Continuous variables will be reported as means with standard deviations (or medians with Interquartile ranges
2065 if skewed). Categorical variables will be reported as counts and percentages.

2066 Measurements will include 24-hour Ambulatory blood pressure measurements (mean diurnal, mean nocturnal
2067 and overall 24-hour average readings for both diastolic and systolic blood pressure) as well as the 'clinic/bed-
2068 side' BP measurements made during the study visits will be estimated using a mean difference and 95%
2069 confidence interval with a P-value.

2072 Characteristics of participants

2073 At baseline each group will be described with regards the following characteristics:

- 2074 • Age
- 2075 • Parity
- 2076 • Ethnicity
- 2077 • Socioeconomic status (index of multiple deprivation)
- 2078 • BMI
- 2079 • Smoking history
- 2080 • Family history of gestational hypertension or pre-eclampsia
- 2081 • Prior history of gestational hypertension or pre-eclampsia
- 2082 • Diagnosis – gestational hypertension or pre-eclampsia
- 2083 • Gestation at diagnosis of gestational hypertension or pre-eclampsia (weeks +days)
- 2084 • Duration of antenatal antihypertensive treatment
- 2085 • Gestation at delivery
- 2086 • Percentage with IUGR defined as less than (<) 40th centile abdominal circumference on the fetal
2087 growth scan
- 2088 • Amount of anti-hypertensive treatment at time of randomisation (WHO defined daily dose)

- 2089 • Clinic systolic and diastolic BP at booking/antenatal visit (mmHg)
2090 • Clinic systolic and diastolic BP at the baseline visit (mean of readings 2 + 3; mmHg)
2091
2092 Frequencies and percentages will be reported for categorical variables and for continuous variables, the mean
2093 and standard deviation will be reported if normally distributed, and the median and interquartile range if not.
2094 No formal statistical testing will be applied to test for any difference between randomised groups with respect
2095 to the above baseline characteristics.

2096
2097 For salt intake, this will be classified as (low/moderate/high), based on self-reported answers to the British
2098 Heart Foundation validated diet questionnaire [38] contained within the POP-HT Lifestyle and diet
2099 questionnaire. This data is collected after randomisation.

2100
2101 Levels of exercise will be reported based on self-reported questionnaire answers (number of minutes per
2102 week) and by objective accelerometer measurement of activity (sedentary/mildly active/moderately
2103 active/highly active) [39]. This data is also collected after randomisation.

2104 **Definition of population for analysis**

2105
2106 The analysis will be carried out on the basis of intention-to-treat (ITT). This is, participants will be analysed
2107 according to their allocated randomisation (intervention vs control arm) irrespective of the treatment they
2108 actually receive. Participants with at least one post randomisation outcome will be included in the analysis
2109 population.

2110
2111 Analysis will be conducted on all patients randomised that fulfilled the inclusion and exclusion criteria apart
2112 the following two scenarios:

- 2113 • The formal diagnosis of any ‘secondary’ cause of hypertension such as pheochromocytoma, Conn’s
2114 syndrome, bilateral renal artery stenosis, aortic coarctation or other condition known to influence BP.
2115 This list is not exhaustive and any other co-morbidities that may be contributory to blood pressure
2116 elevation/reduction will be adjudicated by the PI/CI who will remain blinded to randomisation
2117 • The participant withdraws from the trial and withdraws consent retrospectively for data already
2118 collected

2119 **Data Monitoring Committee and Interim Analyses**

2120
2121 A trial steering committee (TSC) will convene prior to the study starting and half-yearly thereafter to review
2122 and address key aspects of the study including the following:

- 2123 • Recruitment
2124 • Safety/adverse event
2125 • Withdrawals
2126 • Data management
2127 • Statistical analysis plan

2128
2129 The TSC will also function as a data safety and monitoring committee (DSMC) for this study.
2130
2131

2132 **6. Primary analysis**

2133 **Primary outcome**

2134 A linear mixed model will be applied to compare the groups with respect to the primary outcome. The model
2135 will include baseline bedside (i.e. clinic) diastolic BP (mean of the 2nd and 3rd bedside diastolic blood
2136 pressures, randomised group and minimisation factors (gestational age at the time of presentation with pre-
2137 eclampsia/gestational hypertension (continuous) and prescription of ACE inhibitor at randomisation) as fixed
2138 effects. Participant will be included as a random effect.

2139
2140 For all participants included in the primary outcome analysis, the mean 24-hour average diastolic blood
2141 pressure will be reported by randomised group. Adjusted mean differences between randomised groups with

2142 95% confidence interval and p value will be estimated from the model for the following comparison: self-
2143 management (intervention) versus usual care (control) at 6 months.

2144

2145 **Missing data**

2146 The rate of missing data is highly relevant and an important factor affecting the final data analysis. The
2147 frequency (with percentage) of losses to follow-up (defaulters and withdrawals) over the study will be
2148 reported by randomised group and compared between the groups.

2149

2150 Any deaths and their causes will be reported separately.

2151

2152 The availability of the outcome data for the primary and secondary outcomes (blood pressure measurements
2153 only) will be summarised by the two randomised groups. The mixed effects model implicitly accounts for
2154 data missing at random, however the data missing mechanism will be explored. A logistic regression model
2155 will explore any association between baseline characteristics and availability of the primary outcome. Any
2156 changes to the assumptions made in the primary analysis i.e. data missing at random, will be considered in a
2157 sensitivity analysis as described below.

2158

2159 Where 24hr BP data is not available or valid (as described in section 4.1), the participant will have missing data
2160 for the primary outcome at that time point. A further sensitivity analysis will include all participants with missing
2161 primary outcome data imputed using multiple imputation.

2162

2163 **Handling outliers**

2164 A possible outlier is defined as a data-point greater than 3 standard deviations from the mean of its
2165 distribution in the variable at the time-point. For outliers that have not already been queried in data cleaning
2166 they will be queried for double-checking at this stage. Valid BP data is defined by NICE NG133[34] as
2167 explain in detail within section 4.

2168

2169

2170

2171 **7. Secondary analysis**

2172 **Secondary objectives**

2173 Secondary Outcomes have been grouped by variable type.

2174

2175 **Continuous variables**

2176 Those secondary outcomes that represent a continuous variable will be reported as a mean and standard
2177 deviation in each group. The mean difference between groups at 6 months and 95% CI will be reported
2178 alongside a P value from the linear mixed model.

2179

2180 Blood pressure based secondary outcomes:

2181 A linear mixed model will be applied to compare the groups with respect to BP outcomes. The model will be
2182 adjusted for baseline BP (bedside) and minimisation factors. Participant will be included as a random effect.
2183 The adjusted mean difference in BP between the groups, 95% CI for adjusted mean difference in BP and P
2184 value will be reported at each post randomisation time point. The unadjusted mean (SD) BP at each time
2185 point will also be reported.

2186

2187 Factors known to influence baseline blood pressure prior to enrolment e.g. age, parity, BMI at booking will be
2188 described as a number and percentage in each group in the baseline characteristics table.

2189

2190 Non-blood pressure based secondary outcomes:

2191 This includes the cardiovascular and cerebrovascular MRI, echo, vascular, and retinal measures listed in
2192 section 4. Adjusted mean differences between randomised groups, 95% confidence interval and p values will
2193 be calculated for the following comparison: self-management (intervention) versus usual care (control).

2194 Given these secondary outcomes are almost all continuous variables, linear regression will be applied with

2195 adjustment for minimisation factors. For any measures that do not satisfy the assumptions of linear regression
2196 a non-parametric test/regression will be carried out.

2197

2198 **Handling missing data**

2199 The rate of missing data is highly relevant and an important factor affecting the final analysis. The rate of
2200 missing values will thus be summarised for each data point relevant the secondary outcomes as described in
2201 section 4 above.

2202

2203 **Handling outliers**

2204 A possible outlier is defined as a data-point greater than 3 standard deviations from the mean of its
2205 distribution in the variable at the time-point. For outliers that have not already been queried in data cleaning
2206 they will be queried for double-checking at this stage.

2207

2208

2209 **8. Sensitivity analysis**

2210 We will perform sensitivity analysis on the primary outcome.

2211 • Antenatal booking blood pressure recorded from the participants' week 12 booking visit to their
2212 midwives will be included as a covariate in the model. The reason we are performing a 2nd adjusted
2213 model is to assess the impact that antenatal values have on the intervention tested in this trial. Some
2214 groups (Hunt et al[40]) argue that pre-eclampsia is merely a progression/acceleration of higher
2215 antenatal blood pressure values, BMI and adiposity and we wish to explore this in POPHT with this
2216 2nd model of adjustment. Data in the pilot SNAP-HT trial did not differ significantly when adjusted
2217 for antenatal booking blood pressure.

2218 • If any baseline factors are associated with missingness then these variable(s) will be included in the
2219 mixed effect model, since the assumptions of the mixed model are missing at random which means
2220 that variables related to missingness should be included as covariates in the model.

2221 • Participants with missing primary outcome measurements at 6 months will have 6-month outcome
2222 imputed using multiple imputation (MI), if necessary.

2223

2224

2225

2226 **9. Tertiary/additional exploratory analysis**

2227 These include:

2228 • EQ-VAS scores and the measure of utility score from the EQ-5D-5L questionnaires at baseline, week 1
2229 and week 6 and 6 months. These scores will be presented as a mean and standard deviation in each
2230 group for each study visit. P values and a 95% confidence interval will be reported for the difference
2231 between the groups

2232 • Readmission number in each arm (re-admissions included will be those related to blood
2233 pressure/complications of the hypertensive pregnancy over the duration of the entire study
2234 participation). These will be presented as an absolute number and percentage for each group of the
2235 study. No P value will be reported.

2236 • Side-effects reported. The side-effects will be those captured via the app for those in the intervention or
2237 during follow up video calls/face-face visits/SMS (self-reported) or in the medical notes (electronic
2238 patient records). As the side effects are being recorded in different ways in the two arms of the trial,
2239 there could be some bias and more reporting of side effects in the intervention arm. We will therefore
2240 reporting the two sources of data separately i.e. the app and other sources. These will be presented as
2241 an absolute number and percentage for each group of the study. No P value will be reported.

2242 • Biomarker levels associated with endothelial dysfunction, which will be reported at baseline and at 6-
2243 12 months as a mean and standard deviation for each arm (hypertensive vs normotensive) with a P
2244 value and a 95% confidence interval will be reported for the difference between the groups.

- Additional exploratory data is being collected on number of participants in each group with a positive COVID swab from time of enrolment to the V4 and on COVID vaccination statuses (number and type of vaccine at the time of the V4).

10. Subgroup analysis and safety analysis

Subgroup analyses

These additional analyses will be performed on the primary outcome. An interaction term for randomised group x subgroup of interest will each be fitted in a linear mixed model, defined for the analysis of the primary outcome (section 6.1). We will report the P value for the interaction term for the subgroup of interest, subgroup specific treatment effects and 95% CI for each subgroup analysis.

- 1st vs 2nd/additional hypertensive pregnancy
- Index of multiple deprivation (IMD) score (split by median score for Oxfordshire vs those above and below the median within this study and/or using national quartiles)
- Ethnicity – White Caucasian vs. Non-White
- PET vs PIH

Safety analysis

Adverse events

Serious adverse events are not expected but any SAEs that occur during participation in the study will be reported as per GCP guidelines and the policy of the University of Oxford. Further detail, definitions of the relevant SAEs, and the policy for reporting them are contained within the protocol.

There are a number of expected admissions/consultations with healthcare providers that will be expected take place as part of the natural history of pre-eclampsia and gestational hypertension during the trial period. These will be classed as ‘Foreseeable Events’ exempt from reporting as SAEs and the list is contained with the protocol.

The number of the number of patients experiencing at least one adverse event as well as the number of events per group will be reported. All AEs are all reviewed periodically during the TSC and DSMC.

11. Validation

The primary outcome and the safety analysis will be independently analysed by a statistician from PCCTU and the secondary outcomes will be validated by the PC-CTU statistician who will re-run the code.

12. Changes to the protocol or previous versions of sap

This is the first version of the SAP but a number of amendments have been made to the protocol since the study began, as a result of the COVID-19 pandemic. These will not affect the SAP per se:

Amendment No.	Protocol Version No.	Date issued	Author(s) of changes	Details of Changes made
